CASE STUDY

Respiratory distress due to tracheal compression by the dilated innominate artery

ABSTRACT: The case reported is of an 88 yr old female with hypertension and respiratory distress. A chest radiograph revealed a widening of the upper mediastinum. Computed tomographic scanning revealed tracheal compression by the innominate artery, which was elongated and curved. After intubation, she was treated with antihypertensive drugs. This resulted in the remarkable recovery of the patient from respiratory distress. To the authors’ knowledge, this is the first reported case of respiratory distress owing to tracheal compression by elongation and curvature of the innominate artery.

Case report

An 88 yr-old female was admitted to the authors’ hospital complaining of dyspnoea and cough. She was previously diagnosed as having bronchial asthma, and medication was occasionally prescribed. She had been hypertensive and had atrial fibrillation for >10 yrs, but there was no history suggestive of cardiac failure. Two days before admission she complained of cough and exertional dyspnoea. Her symptoms worsened, and she consulted the authors’ emergency clinic on January 23, 1998.

Upon physical examination, her heart rate was irregular at 100 beats-min⁻¹, blood pressure was 224/120 mmHg, and body temperature was 37.0°C. Auscultation of heart sounds revealed systolic regurgitant murmur. Wheezing was audible on the neck, but no rales were detected in either lung. Analysis of arterial blood gases revealed a pH of 7.41, arterial oxygen tension (P$_{a,O_2}$) 9.2 kPa (69 mmHg), and arterial carbon dioxide tension (P$_{a,CO_2}$) 5.3 kPa (40.2 mmHg). Laboratory analysis of blood revealed haemoglobin 129 g·L⁻¹, haematocrit 39%, and white blood cell count 6.250 cells·µL⁻¹, with 54.8% neutrophils, 2.4% eosinophils, 6.4% monocytes, and 34.5% lymphocytes. C-reactive protein (CRP) was 0.2 mg·L⁻¹.

A chest radiograph revealed a widening of the upper mediastinum and cardiomegaly (fig. 1). Bronchoscopy showed a narrowing, with pulsatile compression at the upper portion of the trachea. Computed tomography of the chest demonstrated elongation of the innominate artery, which compressed the upper portion of the trachea (fig. 2).

The patient was endotracheally intubated and put on a respirator, and showed remarkable improvement. No wheezing was heard on examination. She was treated with antihypertensive drugs. On the third day after admission, she was weaned from the ventilator, and was discharged on the 10th day. Her symptoms remained stable over the following 2 months with a treatment aimed at optimal blood pressure control.

Discussion

Acute respiratory distress with tracheal obstruction owing to extrinsic compression has been reported in patients with aneurysms of the aorta and vascular anomalies, including a vascular ring. Some of these were also in conjunction with dilatation of the brachiocephalic artery [3]. Severe tracheal compression by the aneurysm of the ascending aorta has also been described [4, 5]. Two further cases of fatal acute laryngeal compression by the haematoma following rupture of thoracic aortic aneurysms have been reported [7]. However, respiratory distress owing to compression of the trachea by the innominate artery without aneurysm has not to the authors’ knowledge been described previously.

Because the compression of the trachea by the innominate artery appeared to be a result of the hypertension, the patients’ blood pressure was corrected. The patient had no recurrence of respiratory distress during the 2 months of follow-up. Considering the patient’s age and condition, surgical intervention would have been hazardous. However, expandable intraluminal metal stents could have been used to relieve her symptoms, despite a potentially fatal complication of stenting in this situation, including pressure necrosis leading to a bronchoarterial fistula. It was concluded that the cause of the tracheal compression may be the high pressure in the innominate artery, and that medical management aimed at optimal control of blood pressure would appear to be the most appropriate course.
