To the Editor:

We read with interest study by GERI et al. [1], in which the authors have demonstrated a strong agreement between negative nasopharyngeal (NPs)/nasal (Ns) swab and bronchoalveolar lavage (BAL) real-time reverse transcriptase-polymerase chain reaction (rRT-PCR) in the diagnosis of coronavirus disease 2019 (COVID-19) among hospitalised patients. The study findings contradicted earlier reports [2] and suggested a limited utility of BAL. However, the results need to be interpreted comprehensively before drawing any conclusion.
