Abstract

The Global Initiative for Asthma (GINA) Strategy Report provides clinicians with an annually updated evidence-based strategy for asthma management and prevention, which can be adapted for local circumstances (e.g. medication availability). This article summarizes key recommendations from GINA 2021, and the evidence underpinning recent changes.

GINA recommends that asthma in adults and adolescents should not be treated solely with short-acting β_2 -agonist (SABA), because of the risks of SABA-only treatment and SABA overuse, and evidence for benefit of inhaled corticosteroids (ICS). Large trials show that as-needed combination ICS–formoterol reduces severe exacerbations by $\geq 60\%$ in mild asthma compared with SABA alone, with similar exacerbation, symptom, lung function, and inflammatory outcomes as daily ICS plus as-needed SABA.

Key changes in GINA 2021 include division of the treatment figure for adults and adolescents into two tracks. Track 1 (preferred) has low-dose ICS–formoterol as the reliever at all steps: as needed only in Steps 1–2 (mild asthma), and with daily maintenance ICS–formoterol (maintenance-and-reliever therapy, “MART”) in Steps 3–5. Track 2 (alternative) has as-needed SABA across all steps, plus regular ICS (Step 2) or ICS–long-acting β_2 -agonist (Steps 3–5). For adults with moderate-to-severe asthma, GINA makes additional recommendations in Step 5 for add-on long-acting muscarinic antagonists and azithromycin, with add-on biologic therapies for severe asthma. For children 6–11 years, new treatment options are added at Steps 3–4.

Across all age groups and levels of severity, regular personalized assessment, treatment of modifiable risk factors, self-management education, skills training, appropriate medication adjustment, and review remain essential to optimize asthma outcomes.

Introduction

Asthma is a serious global health problem affecting all age groups [1]. Its prevalence has increased in many countries, especially among children. The Global Initiative for Asthma (GINA) aims to improve the diagnosis, management, and prevention of asthma by providing an up-to-date evidence-based strategy and tools and practical resources for clinicians worldwide.

GINA was established through a 1993 collaboration between the World Health Organization (WHO) and the US NHLBI to develop a strategy for the diagnosis and management of asthma [2]. The Global Strategy for Asthma Management and Prevention (GINA strategy report) has been updated annually since 2002 to provide clinicians with up-to-date, evidence-based recommendations as new evidence emerges and new therapies are approved. The GINA strategy report is under continual review by the Science Committee. GINA methodology [3] involves evaluation of new evidence identified from a twice-yearly rolling review of original research and systematic reviews (not limited to specific population/intervention/comparison/outcomes questions), assessment of its impact on existing or new recommendations, and consideration of whether and how it should be integrated into the overall asthma management strategy. GINA is independent of industry.

This article summarizes key recommendations from the 2021 GINA strategy report [4], published in April 2021, and briefly summarizes the evidence and rationale for recent important changes (box 1).

Asthma management during the COVID-19 pandemic

Most studies have shown that patients with asthma are not at increased risk of acquiring coronavirus disease 2019 (COVID-19) or of severe COVID-19. Advise patients to continue taking their prescribed asthma medicines, including inhaled corticosteroids (ICS), alone or in combination with a long-acting β_2 -agonist (LABA), and biological therapy for severe asthma.

Avoid the use of nebulizers, where possible, because of the risk of viral transmission. Within healthcare facilities, follow local infection control procedures and COVID-19 testing recommendations if spirometry, peak expiratory flow (PEF) measurement, or other aerosol-generating procedures (*e.g.* oxygen therapy, sputum induction, ventilation) are needed.

GINA recommends COVID-19 vaccination for people with asthma, with usual precautions including checking for allergies to vaccine ingredients. Anaphylaxis to foods, insect venom, or medications is not a contraindication. Consider giving the first dose of asthma biologic therapy on a different day from the COVID-19 vaccine.

Definition, description, and diagnosis of asthma

Asthma is a heterogeneous disease defined by the history of respiratory symptoms (*e.g.* wheeze, shortness of breath, chest tightness, and cough) that vary over time and in intensity, together with variable expiratory airflow limitation. Airflow limitation may later become persistent.

Asthma is usually associated with airway hyperresponsiveness and airway inflammation, but these are not necessary or sufficient for diagnosis. Clinical phenotypes (*e.g.* childhood onset *versus* late onset, allergic *versus* nonallergic) do not correlate strongly with specific pathological processes or treatment responses.

The diagnosis of asthma is based on a history of characteristic symptom patterns and evidence of variable expiratory airflow limitation obtained from bronchodilator reversibility testing or from other tests, such as a positive bronchial provocation test result, excessive variability during PEF monitoring, excessive variation in FEV₁ between visits, or a significant increase in FEV₁ after ICS treatment (table E1 in the supplementary material). Explain to patients that often, more than one of these tests is needed [5]. Evidence for the diagnosis of asthma should be confirmed before starting controller treatment, if possible, to avoid inappropriate treatment or missing other important diagnoses and because diagnosis is often more difficult later. Results from clinical examination, including chest auscultation, may be completely normal.

The concentration of fractional exhaled nitric oxide (F_{eNO}) is higher in asthma with type 2 airway inflammation but is also higher in atopy, allergic rhinitis, eczema, and eosinophilic bronchitis, and it is lower during bronchoconstriction and in some asthma phenotypes (*e.g.* neutrophilic asthma). It can be increased or decreased by viral respiratory infections.

Additional strategies may be needed to confirm the diagnosis of asthma in particular populations, including patients already on controller treatment (box 1-3 in reference 4), the elderly, smokers, and those in low-resource settings. The differential diagnosis of asthma varies by age (box 1-5 in reference 4).

BOX 1 Key recommendations

- 1) **Diagnosis:** In adults, adolescents, and children ≥ 6 years, confirm the diagnosis of asthma before starting controller treatment, whenever possible, as it is often more difficult afterward. In children ≤ 5 years, recurrent wheezing is common, but asthma is more likely if they have wheezing or coughing with exercise/laughing/crying or in the absence of respiratory infections and if they have a history of eczema or allergic rhinitis.
- 2) **Personalized assess–treat–review cycles:** Asthma management should be personalized and adjusted in a continual cycle of assessment, treatment, and review to minimize symptoms and prevent exacerbations. Consider symptom control, risk factors for exacerbations and side effects, lung function, comorbidities, self-management skills, and patient and/or caregiver goals, preferences, and satisfaction.
- 3) **Comprehensive care:** Asthma management is not “one-size-fits-all.” It includes not only medication but also treatment of modifiable risk factors and comorbidities, nonpharmacological strategies, and education and skills training, particularly for inhaler technique and adherence.
- 4) **Inhaled corticosteroids (ICS):** Asthma in adults and adolescents should not be managed solely with short-acting β_2 -agonists (SABAs). Instead, to reduce the risk of severe exacerbations, and to control symptoms, all adults and adolescents with asthma should be treated with ICS-containing therapy: either regularly every day or, in mild asthma, with ICS–formoterol taken as needed for symptom relief. ICS-containing treatment is also recommended for all children 6–11 years with asthma: either regularly or, in mild asthma, by taking ICS whenever SABA is taken. The past distinction between “intermittent” and “mild persistent” asthma was arbitrary and does not indicate a differential response to ICS.
- 5) **Treatment tracks:** In 2021, for clarity, the Global Initiative for Asthma treatment for adults and adolescents was divided into two tracks, depending on the inhaled reliever medication. Across the five steps, treatment may be stepped up or down within a track, by using the same reliever at each step, or may be switched between tracks, according to the patient’s needs and preferences:
 - **Track 1, with low-dose ICS–formoterol as the reliever.** This is the overall preferred approach because it reduces the risk of severe exacerbations, compared with using a SABA reliever (with/without a maintenance controller), while achieving similar symptom control, similar lung function, and a lower oral corticosteroid burden. In Steps 1–2, there are additional reasons for preferring as-needed-only ICS–formoterol over as-needed SABA (alone or with daily ICS): 1) patients with “mild” asthma can have severe exacerbations; 2) adherence with daily ICS is almost universally poor in patients with mild or infrequent symptoms, leaving them at higher risk of severe exacerbations; and 3) starting treatment with SABA alone trains patients to regard it as their main asthma treatment. As-needed-only ICS–formoterol (without maintenance treatment) in Steps 1–2 should be distinguished from maintenance-and-reliever therapy (MART)[#] in Steps 3–5, in which patients also take ICS–formoterol as daily maintenance treatment. MART is also an option for children 6–11 years in Steps 3–4. ICS–formoterol should not be used as a reliever for patients taking a combination of a non-formoterol ICS–long-acting β_2 -agonist, with/without a long-acting muscarinic antagonist.
 - **Track 2, with SABA as the reliever.** This is an alternative approach (e.g. if Track 1 is not possible or is not preferred by a patient with no exacerbations in the past year). However, before considering a regimen with a SABA reliever, consider whether the patient is likely to adhere to controller therapy. If not, they will be exposed to the risks of SABA-only treatment. For Step 1, taking ICS whenever SABA is taken is preferable to taking SABA alone.
For either track, the Global Initiative for Asthma provides an integrated approach and decision tree for difficult-to-treat and severe asthma, with add-on therapies recommended in Step 5 for severe asthma, including biologic therapy guided by the inflammatory phenotype.
- 6) **Children ≤ 5 years:** Manage wheezing episodes initially with inhaled SABA. Consider trialling controller therapy (e.g. for 3 months) if the symptom pattern suggests asthma, alternative diagnoses have been excluded, and respiratory symptoms and/or wheezing episodes are frequent or severe.
- 7) **Stepping up:** Before stepping up treatment to control symptoms or prevent exacerbations, confirm that the symptoms are due to asthma, identify and address modifiable risk factors (including incorrect inhaler technique, poor medication adherence, environmental exposures, and multimorbidity), and provide patient education.
- 8) **Stepping down:** Once asthma is well controlled for 2–3 months, consider stepping down gradually to find the minimum effective dose, monitoring the patient frequently. Step up again if needed.
- 9) **Asthma action plans:** As part of supported asthma self-management, provide a personalized written asthma action plan for all patients, tailored to their health literacy, so they know how to recognise and respond to worsening asthma.

Continued

BOX 1 Continued

10) **Referral:** Refer patients for expert advice if any of the following apply:

- The diagnosis of asthma cannot confidently be confirmed. For children ≤ 5 years, strongly consider referral for further diagnostic investigations if there is a very early onset of symptoms, failure to respond to treatment, or features suggesting alternative diagnoses (e.g. hypoxaemia, finger clubbing, failure to thrive).
- Occupational asthma is suspected.
- The patient has any risk factors for asthma-related death.
- Symptoms or exacerbations remain uncontrolled despite medium/high-dose ICS–long-acting β_2 -agonist.
- The patient needs urgent healthcare or oral corticosteroids more than once a year.
- There is evidence or high risk of treatment side effects.
- Food allergy is suspected.

#: also called single-inhaler maintenance-and-reliever therapy (SMART).

Assessment of asthma

Asthma control is defined as the extent to which the features of asthma are apparent or have been reduced or eliminated by controller treatment [6]. Assess asthma control within two domains: symptom control and risk of adverse outcomes, particularly exacerbations.

Symptom control

Assess symptom control from asthma-related symptom frequency, night waking and activity limitation, and, for patients using short-acting β_2 -agonist (SABA) reliever, the frequency of SABA use (figure 1). Other symptom control tools include the Asthma Control Test [7] and the Asthma Control Questionnaire (preferably the five-item version) [8].

Rationale

Historically, the frequency of SABA reliever use (≤ 2 or > 2 days per week) was included in the composite assessment of symptom control. This distinction was arbitrary and was based on the assumption that if a SABA was used on > 2 days in a week, the patient needed to start controller therapy or increase the dose. However, if a patient uses as-needed ICS–formoterol as their reliever on average > 2 days per week, this is already providing additional controller therapy, so further dose escalation may not be needed. Therefore, use of ICS–formoterol reliever ≤ 2 versus > 2 days per week is not included in the composite assessment of symptom control. Instead, the average frequency of ICS–formoterol use over the past 4 weeks should be assessed separately when the patient's maintenance controller dose is reviewed.

Risk factors

Assess every patient's risk of exacerbations, even when symptom control is good. Although patients with poor symptom control are more likely to have exacerbations, patients with few or no symptoms can still have severe or even fatal exacerbations, including with external triggers such as viral respiratory infections [9]. Factors that increase a patient's risk of exacerbations even if they have few symptoms include one or more exacerbations in the previous year, overuse of SABA (e.g. $\geq 3 \times 200$ -dose albuterol (salbutamol) canisters per year; i.e. average more than daily use), inadequate ICS use (undertreatment, poor adherence, incorrect inhaler technique), some comorbidities (including obesity, chronic rhinosinusitis, gastroesophageal reflux, confirmed food allergy), a low FEV₁, a high blood eosinophil count in patients with type 2 inflammation, and major psychological or socioeconomic problems. Also assess risk factors for persistent airflow limitation and medication side effects (figure 1).

Lung function testing

Record lung function at diagnosis, 3–6 months after starting treatment, and then periodically (e.g. at least once every 1–2 years; more often in at-risk patients and those with severe asthma) to identify progressive decline. Lung function at individual visits is of limited use for guiding treatment because of its large (up to 20%) visit-to-visit variation [10]. Investigate further if there are few symptoms but impaired lung function is present, which may indicate poor perception [11] or long-term adaptation, or if there are frequent symptoms despite good lung function, which may indicate an alternative cause for the symptoms (box 1-5 in reference 4).

A. Asthma symptom control		Level of asthma symptom control		
In the past 4 weeks, has the patient had:		Well controlled	Partly controlled	Uncontrolled
• Daytime asthma symptoms more than twice/week?	Yes ☐ No ☐	None of these	1–2 of these	3–4 of these
• Any night waking due to asthma?	Yes ☐ No ☐			
• SABA reliever for symptoms more than twice/week?*	Yes ☐ No ☐			
• Any activity limitation due to asthma?	Yes ☐ No ☐			
B. Risk factors for poor asthma outcomes				
<p>Assess risk factors at diagnosis and periodically, particularly for patients experiencing exacerbations.</p> <p>Measure FEV₁ at start of treatment, after 3–6 months of controller treatment to record the patient's personal best lung function, then periodically for ongoing risk assessment.</p>				
<p>Having uncontrolled asthma symptoms is an important risk factor for exacerbations.</p> <p>Additional potentially modifiable risk factors for flare-ups (exacerbations), even in patients with few symptoms[†] include:</p> <ul style="list-style-type: none"> • Medications: high SABA use (associated with increased risk of exacerbations and mortality particularly if $\geq 1 \times 200$-dose canister per month); inadequate ICS: not prescribed ICS; poor adherence; incorrect inhaler technique • Other medical conditions: obesity; chronic rhinosinusitis; GERD; confirmed food allergy; pregnancy • Exposures: smoking; allergen exposure if sensitized; air pollution • Context: major psychological or socioeconomic problems • Lung function: low FEV₁, especially <60% predicted; high BD reversibility • Other tests in patients with Type 2 inflammation: blood eosinophils; elevated FeNO (in adults with allergic asthma taking ICS) <p>Other major independent risk factors for flare-ups (exacerbations)</p> <ul style="list-style-type: none"> • Ever intubated or in intensive care unit for asthma • ≥ 1 severe exacerbation in last 12 months 				
<p>Risk factors for developing persistent airflow limitation</p> <ul style="list-style-type: none"> • History: preterm birth, low birth weight and greater infant weight gain; chronic mucus hypersecretion • Medications: lack of ICS treatment in patients who had a severe exacerbation • Exposures: tobacco smoke; noxious chemicals; occupational exposures • Investigations: low initial FEV₁; sputum or blood eosinophilia 				
<p>Risk factors for medication side-effects</p> <ul style="list-style-type: none"> • Systemic: frequent OCS; long-term, high dose and/or potent ICS; also taking P450 inhibitors • Local: high dose or potent ICS; poor inhaler technique 				

Having any of these risk factors increases the patient's risk of exacerbations even if they have few asthma symptoms

FIGURE 1 Global Initiative for Asthma assessment of asthma control in adults, adolescents, and children 6–11 years. For a version of this figure with full reference citations, please see box 2-2 in reference 4. P450 inhibitors include cytochrome P450 inhibitors such as ritonavir, ketoconazole, and itraconazole. *: based on SABA (as-needed ICS–formoterol reliever not included); excludes reliever taken before exercise. For children 6–11 years, see also box 2-3 in reference 4. For specific risk reduction strategies, see box 3-8 in reference 4. [†]: “independent” risk factors are those that are significant after adjustment for the level of symptom control. Reproduced by permission from reference 4 (box 2-2). BD: bronchodilator; F_{eNO}: fractional exhaled nitric oxide; GERD: gastroesophageal reflux disease; ICS: inhaled corticosteroid; OCS: oral corticosteroid; SABA: short-acting β_2 -agonist.

FIGURE 2 Personalized asthma management cycle of care. Reproduced by permission from reference 4 (box 3-2).

Asthma severity

By consensus [6], asthma severity is assessed retrospectively, after at least 2–3 months of treatment, from the level of treatment required to control symptoms and exacerbations. GINA does not distinguish between so-called “intermittent” and “mild persistent” asthma because this historical distinction was arbitrary, with no evidence of a difference in the treatment response. Severe asthma is asthma that remains uncontrolled despite optimized treatment with high-dose ICS–LABA or that requires such treatment to prevent it from becoming uncontrolled [12]. It is important to distinguish between severe asthma and difficult-to-treat asthma (*i.e.* asthma that may be uncontrolled because of other factors, such as incorrect inhaler technique, poor adherence, and comorbidities such as obesity and environmental exposures) [13].

Rationale

This definition of asthma severity works well at the severe end of the spectrum but is less useful for describing mild asthma (see section “Topics requiring further research”). For example, patients with infrequent or no interval symptoms can still have severe exacerbations. This risk is reduced to a similar extent by either daily ICS treatment [14, 15] or by ICS–formoterol taken only for symptom relief [15], and the baseline symptom frequency does not predict the need for daily ICS [15, 16].

General principles of asthma management

The goals of asthma management are to achieve good symptom control, relieve symptoms when they occur, and minimize the risk of exacerbations and asthma-related death, persistent airflow limitation, and side effects of treatment. The patient’s own treatment goals should be identified because they may be different. Effective asthma management requires a partnership between the patient (or parent/caregiver) and healthcare providers, with shared decision-making and good communication.

Asthma management is not “one-size-fits-all” but instead should be personalized and adjusted in a continual cycle of assessment, treatment adjustment, and review (figure 2).

Assessment

Assess not only symptom control and lung function but also the individual’s modifiable risk factors and comorbidities (also called “treatable traits”) [17], and patient/parent goals and preferences. Check adherence and inhaler technique frequently. Poor symptom control is associated with a much higher risk of exacerbations, but patients with apparently mild asthma or with good symptom control can still have severe or life-threatening exacerbations [9, 14, 18].

Treatment adjustment

Treatment adjustment includes not only changes in the asthma medication dose or type but also multidisciplinary management of modifiable risk factors and comorbidities (section 3D in reference 4) and

nonpharmacological strategies such as smoking cessation and avoidance of indoor/outdoor air pollution (box 3-9 in reference 4).

For all patients, provide regular training in inhaler techniques and asthma self-management, including self-monitoring of symptoms and/or PEF, and a written asthma action plan [19] (section 3C in reference 4). Encourage adherence with controller medication, even when symptoms are infrequent. Consider stepping down treatment when good control has been maintained for 2–3 months (box 3-7 in reference 4).

Review

Arrange regular medical review to identify modifiable risk factors, optimize care, and minimize the risk of exacerbations; review at least yearly (more often in patients with moderate or severe asthma), after an exacerbation, and after a treatment change. Review clinical outcomes and side effects, patient/parent/caregiver satisfaction, inhaler technique and self-management skills. Ensure the patient/caregiver has an up-to-date written asthma action plan.

Rationale

The GINA strategy (figure 2) considers not only patient characteristics that may predict a clinically important difference in treatment response but also medication access, the patient's preferences, and practical issues of cost, ability to use the inhaler, and likely adherence. The extent to which asthma treatment can be individualized according to patient characteristics or phenotype depends on the health system, the clinical context, evidence about the magnitude of potential difference in outcomes, cost, and available resources.

Medications and strategies for symptom control and risk reduction

Asthma medications are categorized as controllers, relievers, and add-on therapies:

- **Controllers** contain ICS, which reduce airway inflammation, control symptoms, and reduce the risks of exacerbations [20], even in mild asthma [14, 15, 21], and of asthma death [22]. Treatment with ICS may reduce exacerbation-related declines in lung function [23]. “Maintenance” therapies are controllers that are prescribed for daily use.
- **Relievers** (low-dose ICS–formoterol or SABA) contain rapid-onset bronchodilators. They are used “as needed” (*i.e.* for quick relief of symptoms, including during exacerbations). Using ICS–formoterol as a reliever (often called an “anti-inflammatory reliever” or “AIR”) also reduces the risk of severe exacerbations, compared with a SABA reliever, both with [24, 25] or without [15, 21] maintenance controller treatment. SABA or ICS–formoterol is also recommended before exercise if needed to prevent exercise-induced bronchoconstriction [26, 27].
- **Add-on therapies** are mainly for patients with difficult-to-treat or severe asthma (see below).

When choosing medications, consider local guidelines, regulatory approvals, and payer criteria.

Recommendation against SABA-only treatment

Since 2019, GINA has recommended against SABA-only treatment of asthma in adults and adolescents after consideration of its risks and the evidence for a safer alternative [28]. Instead, to reduce the risk of serious exacerbations and control symptoms, all adults and adolescents with asthma should receive ICS-containing treatment, either regularly or, in mild asthma, as needed to relieve symptoms [28]. ICS is now also recommended for all children 6–11 years with asthma, either regularly or, in mild asthma, whenever SABA is taken for symptom relief.

Rationale

Although SABA is inexpensive and relieves symptoms quickly, treatment of asthma with SABA alone is associated with increased risk of asthma-related death [22] and of urgent asthma-related healthcare [20], even in patients with so-called intermittent asthma [29]. Overuse of SABAs ($\geq 3 \times 200$ -dose albuterol canisters per year) is associated with incrementally increasing risk of asthma exacerbations and mortality, including in patients treated with SABA alone [22]. Regular use of SABA, even 2–4 times per day for 1–2 weeks, is associated with β_2 -receptor downregulation, loss of bronchodilator response, increased airway hyperresponsiveness, and increased airway inflammation [30, 31]. Importantly, from a cognitive and behavioural perspective, starting treatment with SABA alone trains the patient to regard it as their main asthma treatment, increasing the challenges for adherence with any subsequent advice to take ICS every day even when asymptomatic.

By contrast, in mild asthma, as-needed ICS–formoterol decreases the risk of severe exacerbations requiring oral corticosteroid (OCS) by $\geq 60\%$ compared with SABA alone [15, 21], including in patients without elevated type 2 inflammatory markers [15, 32], with a very small average daily ICS dose [15, 16, 21, 33].

Adults & adolescents 12+ years

Personalized asthma management

Assess, Adjust, Review
for individual patient needs

CONTROLLER and PREFERRED RELIEVER

(Track 1). Using ICS-formoterol as reliever reduces the risk of exacerbations compared with using a SABA reliever

STEPS 1 – 2

As-needed low dose ICS-formoterol

STEP 3

Low dose maintenance ICS-formoterol

STEP 4

Medium dose maintenance ICS-formoterol

STEP 5

Add-on LAMA
Refer for phenotypic assessment ± anti-IgE, anti-IL5/5R, anti-IL4R
Consider high dose ICS-formoterol

RELIEVER: As-needed low-dose ICS-formoterol

CONTROLLER and ALTERNATIVE RELIEVER

(Track 2). Before considering a regimen with SABA reliever, check if the patient is likely to be adherent with daily controller

STEP 1

Take ICS whenever SABA taken

STEP 2

Low dose maintenance ICS

STEP 3

Low dose maintenance ICS-LABA

STEP 4

Medium/high dose maintenance ICS-LABA

STEP 5

Add-on LAMA
Refer for phenotypic assessment ± anti-IgE, anti-IL5/5R, anti-IL4R
Consider high dose ICS-LABA

RELIEVER: As-needed short-acting β_2 -agonist

Other controller options for either track

	Low dose ICS whenever SABA taken, or daily LTRA, or add HDM SLIT	Medium dose ICS, or add LTRA, or add HDM SLIT	Add LAMA or LTRA or HDM SLIT, or switch to high dose ICS	Add azithromycin (adults) or LTRA; add low dose OCS but consider side-effects
--	--	---	--	---

FIGURE 3 Personalized management for adults and adolescents to control symptoms and minimize risk. For ICS doses, see box 3–6 in reference 4. Reproduced by permission from reference 4 (box 3-5A). HDM: house dust mite; ICS: inhaled corticosteroid; LABA: long-acting β_2 -agonist; LAMA: long-acting muscarinic antagonist; LTRA: leukotriene receptor antagonist; OCS: oral corticosteroid; SABA: short-acting β_2 -agonist; SLIT: sublingual immunotherapy.

Starting treatment with as-needed ICS-formoterol in patients with mild asthma addresses both symptom relief and risk reduction without the need for daily maintenance treatment.

GINA treatment tracks for adults and adolescents

There are five levels of treatment (Steps 1–5; figure 3), with two “tracks,” depending on the choice of reliever: ICS-formoterol (Track 1, preferred) or SABA (Track 2, alternative). Treatment may be stepped up or down within a track by using the same reliever at each step or may be switched between tracks.

Within **Track 1**, the reliever is as-needed, low-dose ICS-formoterol. This means that when a patient at any treatment step has asthma symptoms, they take low-dose ICS-formoterol for symptom relief. In Steps 1–2, this also provides the patient’s controller therapy and reduces severe exacerbation risk [15, 16, 21, 33], without daily maintenance treatment. This is distinguished from maintenance-and-reliever therapy (MART) in Steps 3–5, where patients take ICS-formoterol both as daily maintenance treatment and, as needed, for symptom relief (table 1).

Track 2, with SABA reliever, is suggested where ICS-formoterol is not available or is not preferred by a patient at low risk of exacerbations (including having no exacerbations in the past year). Before prescribing therapy with SABA reliever, consider if the patient is likely to be poorly adherent with ICS controller therapy, as this increases the risk of exacerbations.

In Figure 3, additional or alternative treatments with less evidence for safety, efficacy, and/or effectiveness are shown as “other controller options.”

TABLE 1 Differences between current asthma treatment regimens containing an AIR

	Anti-inflammatory reliever (AIR) therapy alone (GINA Steps 1–2)	Maintenance-and-reliever therapy (MART [#]) (GINA Steps 3–5)
Definition	Combination ICS–formoterol taken as needed for symptom relief, [‡] without maintenance therapy <i>Or, if not available, low-dose ICS taken whenever SABA is taken for symptom relief</i>	Daily maintenance ICS–formoterol <i>PLUS</i> Low-dose ICS–formoterol taken as needed for symptom relief [‡]
Indications	Mild asthma: GINA Steps 1–2	Moderate-to-severe asthma: GINA Steps 3–5
Explanation	Whenever symptom relief is needed, the patient takes an inhaler containing a combination of a low dose of ICS and formoterol (instead of a SABA), without daily maintenance treatment <i>Or, if ICS–formoterol is not available, they take a low dose of ICS whenever SABA is taken</i>	The patient takes regular daily maintenance controller treatment with low-dose (Step 3) or medium-dose (Step 4) combination ICS–formoterol <i>PLUS</i> Whenever needed for symptom relief, the patient uses an inhaler containing a combination of a low dose of ICS and formoterol (instead of a SABA)
Medications and age groups studied	Budesonide–formoterol (≥12 years). There have been smaller studies with beclometasone–albuterol in combination or separate inhalers in adults ≥18 years, adolescents and children ≥4 years	Budesonide–formoterol (ages ≥4 years) Or beclometasone–formoterol (adults ≥18 years)
Rationale	In patients with mild asthma, as-needed-only budesonide–formoterol reduced severe exacerbations by ≥60% compared with SABA alone, with similar symptom control and lung function as maintenance ICS plus as-needed SABA <i>With as-needed-only ICS+SABA in patients with mild asthma, some studies showed fewer exacerbations than SABA alone; other studies showed similar outcomes to physician-adjusted ICS treatment</i>	In moderate-to-severe asthma, MART with ICS–formoterol reduced severe exacerbations compared with the same dose or high-dose ICS or ICS–LABA plus as-needed SABA, with similar symptom control and lung function <i>There have been no studies with ICS+SABA both used as MART, and some evidence suggests that taking ICS+SABA regularly may increase exacerbation risk</i>

GINA: Global Initiative for Asthma; ICS: inhaled corticosteroid; LABA: long-acting β_2 -agonist; LAMA: long-acting muscarinic antagonist; SABA: short-acting β_2 -agonist; SMART: single-inhaler MART. “AIR” is a term used for reliever inhalers that contain a combination of an ICS with either formoterol or albuterol. ICS–formoterol contains a combination of an ICS (e.g. budesonide or beclometasone) and formoterol, a rapid-onset LABA that, for most patients, relieves symptoms and bronchoconstriction as quickly as a SABA. When **budesonide–formoterol** or **beclometasone–formoterol** are used as needed, a single inhalation is taken for symptom relief. If symptoms persist after a few minutes, an additional inhalation can be taken, but no more than six inhalations should be taken on a single occasion (four inhalations of budesonide–formoterol for children 4–11 years). The maximum total dose (reliever inhalations plus maintenance inhalations, if used) that can be used temporarily in a single day is 12 inhalations of budesonide–formoterol for adults/adolescents (total of eight inhalations for children 4–11 years) and a total of eight inhalations of beclometasone–formoterol for adults. If patients need more than this, they should seek medical help the same day. **Other ICS–formoterol formulations** (e.g. mometasone–formoterol, fluticasone propionate–formoterol) have not been studied as anti-inflammatory relievers, either alone or in MART, but could be substituted if budesonide–formoterol or beclometasone–formoterol is not available. Before prescribing any inhaler, ensure that the patient can use it correctly. The recommended maximum doses refer to the maximum total dose that can be taken temporarily on any single day, not the expected or desirable average use. In clinical trials of as-needed budesonide–formoterol in adults and adolescents with mild asthma, patients used an average of only three to four inhalations per week of low-dose budesonide–formoterol, and <0.1% of patients took more than eight inhalations of budesonide–formoterol on more than 1 day during the 12 months of treatment [21, 33]. For all patients prescribed as-needed-only ICS–formoterol or MART, the *average* frequency of as-needed use of ICS–formoterol over the previous 4 weeks should be reviewed at each visit as part of the assessment of their treatment needs, especially when considering the need for maintenance treatment. Combinations of ICS with non-formoterol LABA, or combinations of ICS, LABA, and LAMA, should not be used as needed; they are recommended only for maintenance treatment. For patients using a **non-formoterol ICS–LABA** (with or without a LAMA), the appropriate reliever is SABA. [#]: also called SMART; [‡]: for dosage details, see table E2 and the downloadable resource in the supplementary material.

Rationale

GINA introduced two tracks into the 2021 treatment figure for adults and adolescents (figure 3 and box 3-5A in reference 4) to clarify:

- How to step treatment up or down within the different reliever options (ICS–formoterol or SABA).
 - That SABA is the recommended reliever for patients prescribed maintenance non-formoterol ICS–LABA.
- The Track 1 approach is preferred overall because it reduces the risk of severe exacerbations compared with using a SABA reliever, with similar symptom control and lung function, and it integrates messaging about the importance of both symptom control and risk reduction across all treatment steps, including Step 1. The figure also summarizes the main considerations for choosing ICS–formoterol or SABA as the reliever and reinforces the key elements of personalized asthma treatment.

GINA treatment steps for adults and adolescents

Steps 1 and 2, preferred treatment (Track 1)

The preferred treatment for adults and adolescents with mild asthma is low-dose ICS–formoterol taken as needed for symptom relief, without maintenance treatment (figure 3). As-needed-only ICS–formoterol is usually prescribed with a budesonide–formoterol inhaler providing a metered dose of 200/6 µg per inhalation (equivalent to a delivered dose of 160/4.5 µg), with one inhalation taken as needed for symptom relief (table 1; for dosage details, see table E2 and the downloadable resource in the supplementary material). Other combination ICS–formoterol products may be suitable but have not yet been studied.

Rationale

Considerations for the recommendations at Steps 1 and 2 are interrelated. In patients eligible for Step 2 treatment, two large studies found that as-needed ICS–formoterol reduced the risk of severe exacerbations by almost two-thirds compared with SABA-only treatment [15, 21]. Four studies (~10 000 patients) showed a similar or greater reduction in severe exacerbations compared with daily low-dose ICS, without clinically important differences in symptom control [15, 16, 21, 33], lung function [15, 16, 21, 33], or airway inflammation measured by F_{eNO} [15, 16] over 12 months. The primary outcome variable of one study [21] was “well-controlled asthma weeks”, but this outcome was not considered reliable because it was based on a past definition of asthma control and was systematically biased against the as-needed ICS–formoterol treatment group, in which patients were permitted much less ICS than those on maintenance ICS before a week was classified as not well controlled. In two studies that showed a greater overall reduction in the risk of severe exacerbations with as-needed ICS–formoterol compared with maintenance ICS plus as-needed SABA [15, 16], no predictors of differential response were identified among many baseline characteristics, including inflammatory phenotype [15, 16], except for a clinically unimportant difference in the five-item Asthma Control Questionnaire in one study [16].

In Step 1, the recommendation for as-needed, low-dose ICS–formoterol for adults and adolescents with symptoms less than twice per month is supported by indirect evidence for a large reduction in the risk of severe exacerbations, compared with as-needed SABA alone [15, 21]. Extension of this recommendation to Step 1 was also supported by several important considerations:

- Historically, recommendations for as-needed SABA alone were never supported by evidence of long-term safety or efficacy; early guidelines had assumed that patients with mild asthma would not benefit from ICS and were concerned about its risks based on experience with OCS.
- The past distinction between eligibility for Step 1 and Step 2 treatment based on symptom frequency (e.g. ≤ 2 or > 2 days per week) was arbitrary, not evidence-based.
- The use of as-needed ICS–formoterol markedly reduces severe exacerbations, compared with as-needed SABA, even in patients with SABA use less than or equal to two times per week at baseline (so-called intermittent asthma) [15].
- A single day with more than two, more than four, more than six, or more than eight doses of as-needed budesonide–formoterol reduced the short-term (21-day) risk of severe exacerbations, compared with as-needed SABA alone (*post hoc* analysis) [34]. A similar effect was seen with ICS–formoterol MART in Steps 3–4 [35, 36].
- Even modest overuse of SABA (e.g. dispensing three or more albuterol canisters per year; i.e. average of ≥ 1.6 puffs per day) is associated with an increased risk of severe exacerbations [37, 38] and, in one study, higher asthma mortality [38].
- Even occasional short courses of OCS (e.g. four to five courses over 7 years; i.e. less than one course per year), are associated with significant short-term risks [39] and cumulative risks of long-term adverse effects such as osteoporosis and diabetes [40].
- Regular, daily, low-dose ICS treatment is highly effective in reducing asthma symptoms and risk, including in patients with infrequent symptoms [14], but poor adherence to ICS is common [41], exposing patients to the risks of SABA-only treatment.
- As-needed budesonide–formoterol is well tolerated in mild asthma [15, 16, 21, 33].
- Starting treatment with SABA alone trains the patient to regard it as their primary asthma treatment.

Steps 1 and 2, alternative treatment (Track 2)

The alternative (non-preferred) Step 2 recommendation for adults and adolescents remains regular, low-dose ICS with as-needed SABA. The Step 1 recommendation is taking ICS whenever SABA is taken (combination or separate inhalers).

Rationale

For patients with initial symptoms twice per month or more, low-dose maintenance ICS reduces the risk of serious exacerbations by almost half compared with SABA alone [14]. There is a paucity of evidence for

the safety and effectiveness of as-needed concomitant ICS + SABA, as only small groups received this regimen in studies of adults [42, 43] and children 5–18 years [44, 45]. However, concomitant ICS + SABA would be preferable to using SABA alone if ICS–formoterol is not available or affordable. No data are available about the acceptability to adults of carrying separate ICS and SABA inhalers for symptom relief or on what proportion of patients would revert to SABA-only use. No data are available about safe levels of as-needed ICS + SABA use, but in one study, exacerbations were higher among patients randomized to twice-daily ICS–SABA than among those on as-needed ICS–SABA [42], consistent with risks associated with SABA overuse [38].

Steps 3 and 4

The preferred Step 3 treatment is maintenance-and-reliever therapy (MART) with low-dose ICS–formoterol [24, 25, 46], which is approved in many countries with budesonide–formoterol and beclometasone–formoterol. For Step 4, if needed, the maintenance dose of ICS–formoterol can be increased to medium [36, 47, 48]. The doses of ICS–formoterol recommended for MART, including the maximum dose in any day, are shown in table E2 and the downloadable resource in the supplementary material.

Rationale

In adults and adolescents with poor symptom control and one or more exacerbations in the previous year, MART reduced exacerbations and provided similar symptom control at relatively low ICS doses, compared with maintenance ICS–LABA or higher-dose ICS, both with as-needed SABA [24, 49–51]. In open-label studies in broader populations, MART also significantly reduced severe exacerbations, with a lower average dose of ICS [25, 46]. ICS–formoterol should not be used as the reliever for patients taking maintenance non-formoterol ICS–LABA because there are no data for efficacy and safety.

Step 5

See section “Difficult-to-treat and severe asthma in adults and adolescents”, below.

Choosing initial asthma treatment

When choosing the track and starting step for initial treatment (boxes 3-4A–3-4D in reference 4), consider not only the patient’s current symptoms and risk of exacerbations but also practical issues, including medication access (availability and cost), inhaler technique, likely adherence, and patient preferences. Before starting, record evidence for the diagnosis of asthma, the patient’s symptom control and risk factors, including lung function, and check that they can use the inhaler correctly. Provide education and skills training, and schedule a follow-up visit to assess the response (figure 2).

During ongoing treatment, medication may be adjusted up or down within the same track (*i.e.* with the same reliever) or may be switched between tracks, depending on patient needs. However, for patients prescribed as-needed-only ICS–formoterol (Steps 1–2) or MART (Steps 3–5), beware of risks to the patient if their ICS–formoterol is switched without consultation (*e.g.* in health systems where medication substitution by pharmacists or nurses is permitted) to a combination non-formoterol ICS–LABA, as these are not suitable for as-needed use.

Stepping down to find the minimum effective dose

When good asthma control has been achieved and maintained for 2–3 months, consider stepping down to find the lowest effective step. Do not completely withdraw ICS, except if needed temporarily while confirming the diagnosis of asthma. Adults and adolescents with well-controlled asthma while on daily low-dose controller therapy can step down to either as-needed ICS–formoterol [16, 21, 33] or to as-needed ICS + SABA taken together [42, 43] (box 3-7 in reference 4).

Stepping up if asthma remains uncontrolled

Before considering any sustained step up, first check inhaler technique, adherence, persistent allergen exposure and comorbidities.

There is no evidence to support specific recommendations about when to increase from as-needed-only ICS–formoterol in Steps 1–2 to Step 3 MART by adding maintenance ICS–formoterol, but it should be prompted by factors such as ongoing use of as-needed ICS–formoterol on most days of the week or further exacerbations.

Patients with risk factors for exacerbations

Prescribe an ICS-containing controller, preferably with ICS–formoterol as the reliever, as this reduces the risk of severe exacerbations [15, 16, 21, 24, 25, 33, 46]. Arrange review more frequently than for patients

For MART doses, see table E2 and the downloadable resource in the supplementary material. Reproduced by permission from reference 4 (box 3-5B). BUD-FORM: budesonide-formoterol; ICS: inhaled corticosteroid; LABA: long-acting β_2 -agonist; LTRA: leukotriene receptor antagonist; MART: maintenance-and-reliever therapy; OCS: oral corticosteroid; SABA: short-acting β_2 -agonist.

at low risk. Identify and address modifiable risk factors (e.g. smoking, overuse of SABA, comorbidities) (box 3-8 in reference 4). Consider nonpharmacological strategies, such as smoking cessation advice and trigger avoidance, to improve symptom control and/or reduce risk (box 3-9 in reference 4).

Management of exercise-induced symptoms

For patients with dyspnoea or wheezing on exertion, distinguish between exercise-induced bronchoconstriction and symptoms due to obesity, poor cardiopulmonary fitness, or alternative diagnoses such as inducible laryngeal obstruction. For patients with exercise-induced bronchoconstriction, prescribe ICS-containing controller treatment and advise sufficient warm-up before exercise [26]. Patients using as-needed ICS-formoterol as their reliever (Track 1) can use the same medication before exercise, if needed, and do not need a SABA inhaler [27].

Rationale

For pre-exercise use by adults and adolescents, formoterol was recommended in guidelines for many years as an effective and safe alternative to albuterol [26] but is no longer promoted because of risks of LABA-only treatment. Pre-exercise ICS-formoterol avoids this risk and is as effective as daily ICS plus pre-exercise SABA in reducing exercise-induced bronchoconstriction [27].

GINA steps for children aged 6–11 years

Treatment steps for children are shown in figure 4 (box 3-5B in reference 4). In Step 1, for children with initial symptoms less than twice per month, taking ICS whenever SABA is taken for symptom relief is preferred over regular ICS or as-needed SABA alone. Regular, low-dose ICS with as-needed SABA is recommended in Step 2 for most children with asthma, but attention must be paid to adherence.

In Step 3, options include low-dose ICS–LABA, medium-dose ICS, or very-low-dose budesonide–formoterol MART [52]. In Step 4, options include medium-dose ICS–LABA [53] or low-dose MART (table 1; table E2 and downloadable resource in the supplementary material). For all children at Step 4, consider referral for expert advice. In children, before stepping up, consider trying other controller options at the same step.

Rationale

The addition of as-needed concomitant ICS + SABA as an anti-inflammatory reliever in Step 1 for children was based on evidence from two studies in which children and adolescents were stepped down from maintenance ICS to as-needed ICS plus SABA in separate inhalers [44, 45] and because of likely nonadherence with daily ICS by children with infrequent symptoms. For Step 2, there is much more evidence for the safety and effectiveness of maintenance low-dose ICS, but in the real world, ICS adherence is extremely low. In Step 3, MART with very-low-dose ICS–formoterol [52] was previously recommended in the GINA report text and for consistency is now also included in the figure (box 3-5B in reference 4, and figure 4). For Step 4, doubling the MART maintenance dose to 100/6 µg (delivered dose of 80/4.5 µg) by instructing the patient to take one inhalation twice daily (still “low dose”) was included by consensus, given the variation in ICS responsiveness between patients (table 1; table E2 and downloadable resource in the supplementary material).

Managing asthma with comorbidities and in specific populations

Identify and manage comorbidities such as rhinosinusitis, obesity, and gastroesophageal reflux disease. Multimorbidity contributes to respiratory symptoms and impaired quality of life, and some comorbidities contribute to poor symptom control or exacerbations.

Despite general concerns about medication use in pregnancy, the advantages of actively treating asthma in pregnancy to avoid exacerbations markedly outweigh any potential adverse effects of usual controller and reliever medications [54].

For details of multidisciplinary assessment and management of asthma with comorbidities and in specific settings, see chapter 3D in reference 4.

Diagnosis and initial treatment of patients with features of both asthma and COPD

Asthma and chronic obstructive pulmonary disease (COPD) are umbrella labels for overlapping heterogeneous conditions. Symptoms may be similar, and the diagnostic criteria overlap. Some patients have features of both asthma and COPD (asthma + COPD), particularly smokers and older adults. This is not a single disease entity. It includes several clinical phenotypes that are likely caused by a range of underlying mechanisms.

There are important differences in evidence-based treatment recommendations for asthma [4] *versus* COPD [55], with treatment with long-acting bronchodilators alone (*i.e.* without ICS) recommended as initial treatment in COPD but contraindicated in asthma because of the risk of severe exacerbations and death. Until more discriminatory risk factors are identified, all patients with diagnoses of both asthma and COPD should receive ICS. COPD should be managed according to Global Initiative for Chronic Obstructive Lung Disease [55] recommendations. For all patients, provide education on inhaler technique and adherence and advice about smoking cessation, immunizations, physical activity, and management of comorbidities. Refer for specialist investigations and multidisciplinary care, where possible.

Rationale

The descriptive term “asthma + COPD” is preferred because “asthma–COPD overlap” was often assumed to represent a single disease. Patients with asthma + COPD have a greater burden of symptoms and exacerbations, more impaired quality of life, more rapid decline in lung function, greater need for healthcare use, and higher mortality than patients with asthma or COPD alone [4]. The recommendation for ICS is because several studies have shown that patients with diagnoses of both asthma and COPD are at increased risk of hospitalization or death if they are treated with LABA compared with ICS–LABA [56–58].

Difficult-to-treat and severe asthma in adults and adolescents

Detailed information is provided in the GINA 2021 pocket guide on difficult-to-treat and severe asthma [13], including an integrated decision tree for diagnosis and management across primary and specialist care. A brief summary is included below.

Assessment and optimization of therapy

Difficult-to-treat asthma is asthma that is uncontrolled despite medium- or high-dose ICS–LABA treatment or that requires high-dose ICS–LABA treatment to maintain good symptom control and reduce exacerbations.

Severe asthma is asthma that is uncontrolled despite good adherence with optimized high-dose ICS–LABA therapy and management of contributory factors or that worsens when high-dose treatment is decreased. Approximately 3–10% of people with asthma have severe asthma [12, 59].

Assess all patients with difficult-to-treat asthma to confirm the diagnosis of asthma and to identify and manage factors that commonly contribute to symptoms, poor quality of life, and/or exacerbations. For patients with persistent symptoms and/or exacerbations despite high-dose ICS–LABA, assess the clinical and inflammatory phenotype, as this may guide the selection of add-on treatment. Refer for expert advice if asthma does not improve in response to optimizing Step 4 or 5 treatment (or earlier, if needed).

Management of severe asthma

Refer patients to support services, where available, to help them deal with the heavy physical, emotional, social and financial burden of severe asthma and its treatment [60].

In Step 5, recommended add-on options include long-acting muscarinic antagonist (LAMA) (tiotropium ≥ 6 years, triple therapy with ICS–LABA–LAMA ≥ 18 years). Adding LAMA provided modest improvement in lung function but not symptom control, and exacerbations were reduced in some studies [61–65]. Step 4 MART with ICS–formoterol should be tried before considering add-on LAMA; as-needed ICS–formoterol can be continued as the reliever for patients prescribed ICS–formoterol–LAMA, but for patients prescribed an ICS–LABA–LAMA with non-formoterol LABA, the appropriate reliever is SABA. After specialist referral, add-on, low-dose azithromycin is another option for reducing exacerbations, but risks of antibiotic resistance and prolongation of the corrected QT interval (QTc) on electrocardiography must be considered [66]. Sputum-guided adjustment of the ICS dose improves outcomes in moderate-to-severe asthma [67] but is not widely available, and the optimal frequency of sputum assessment is not known.

With add-on biologic therapies for severe eosinophilic asthma (benralizumab, dupilumab, mepolizumab, reslizumab) and severe allergic asthma (dupilumab, omalizumab) the main benefits are substantial reduction in severe exacerbations and reduced OCS exposure [68]. No head-to-head studies are available, but typical eligibility criteria for each class, and predictors of good response, are found in the GINA pocket guide decision tree [13].

Maintenance OCS treatment should be avoided, wherever possible, because of its serious long-term side effects [40, 69].

At follow-up, assess the response to any add-on treatment, stop ineffective treatments, and consider other options. For patients who respond to add-on therapy, re-evaluate the need for other therapies every 3–4 months, but do not completely stop ICS.

Continue to optimize patient care in collaboration with primary care and consider the patient's social and emotional needs. Arrange multidisciplinary team care for severe asthma, if available. Invite patients with severe asthma to enrol in a registry or clinical trial, if available and relevant, to help fill evidence gaps, including comparison of biologic therapy options and positioning of bronchial thermoplasty [68].

Management of worsening asthma and exacerbations

Asthma exacerbations represent acute or subacute worsening in symptoms and lung function from the patient's usual status. In some cases, a patient may present for the first time during an exacerbation.

For discussion with patients, use terminology that is easily understood; “flare-up” is more patient-friendly than the academic term “exacerbation.” The terms “episodes”, “attacks” and “acute asthma” are often used, but their meanings vary widely [70].

Preventing severe exacerbations that require treatment with systemic corticosteroids is an important goal of asthma management. Even a single OCS course has significant adverse effects [39], and taking as few as 4–5 courses of OCS over 7 years' follow-up is associated with increased risk of serious long-term conditions, including osteoporosis, pneumonia, cardiovascular disease, cataracts, renal impairment, diabetes, and weight gain [40, 69]. Key strategies for reducing exacerbations include ICS-containing treatment (particularly as-needed-only ICS–formoterol and MART), managing risk factors, and providing a

personalized written asthma action plan. The reduction in asthma exacerbations seen in many countries during the COVID-19 pandemic suggests that public health measures to reduce spread of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infections (*e.g.* handwashing, social/physical distancing, mask-wearing) may be important in reducing transmission of other respiratory viruses.

Patients at increased risk of asthma-related death should be identified and reviewed more frequently. Factors include a history of requiring intubation and mechanical ventilation, having a hospitalization or emergency department (ED) visit for asthma in the previous year, not currently using or poorly adherent with ICS-containing therapy, overuse of SABAs [38], a history of psychiatric disease or psychosocial problems, concomitant food allergy, and currently using or having recently stopped OCS (a marker of exacerbation severity) (box 4-1 in reference 4).

Written asthma action plans

As part of asthma self-management, provide all patients with a written asthma action plan appropriate for their level of asthma control and health literacy, so they know how to recognise and respond to worsening asthma [19]. State when and how to change reliever and controller medications, use OCS if appropriate, and access medical care if symptoms fail to respond to treatment. Base the action plan on changes in symptoms or (only in adults) PEF [19].

Advise patients who have a history of rapid deterioration to go to an acute care facility or see their doctor immediately if their asthma starts to worsen.

Action plan recommendations for responding to worsening asthma depend on the patient's usual therapy. Patients prescribed as-needed ICS-formoterol as their reliever, either alone or in MART, should increase their as-needed doses as symptoms increase. Those on a maintenance ICS-containing controller should increase to a high dose temporarily (*e.g.* for 1–2 weeks) (box 4-2 in reference 4).

Rationale

In a systematic review of self-management studies, action plans in which the ICS dose was at least doubled were associated with improved asthma outcomes and reduced healthcare use [71]. In some studies in adults and adolescents [19, 72] and preschool children [73], short-term, higher-dose ICS reduced progression to a severe exacerbation, and some found less impact on serum cortisol than with OCS [74, 75], but cost may be an issue. Given the shape of the ICS dose–response curve, the benefit of increasing maintenance ICS when asthma worsens may be greater when background adherence is lower. The timing of an increased ICS dose may be important: studies in adults in which the ICS dose was doubled 5–7 days after symptoms worsened found no reduction in severe exacerbations [76, 77]. In contrast, in MART, taking reliever doses of ICS-formoterol as soon as asthma symptoms occur, reduces the risk of progression to severe exacerbation [24, 25].

Management of exacerbations in a primary care or acute care facility

Assess exacerbation severity from the patient's mental state, degree of dyspnoea, vital signs, oxygen saturation, and lung function (PEF or spirometry) while starting treatment with repeated administration of SABA (in most patients, by pressurized metered-dose inhaler and spacer) and controlled flow oxygen (sufficient flow to maintain oxygen saturation at 93–95% for adults, 94–98% for children 6–11 years), if available (figure 5). Controlled oxygen therapy is associated with lower mortality and better outcomes than high-concentration (100%) oxygen therapy [78–80].

Arrange immediate transfer to an acute care facility if there are signs of severe exacerbation, or to intensive care, particularly if the patient is drowsy, confused, or has a silent chest. During transfer, give inhaled SABA and ipratropium bromide, controlled oxygen, and systemic corticosteroids.

Repeated administration of albuterol (up to 4–10 puffs every 20 min for the first hour) is effective for rapidly reversing airflow limitation [81]. Avoid nebulization except for life-threatening asthma; delivery of rapid-acting β_2 -agonist *via* a pressurized metered-dose inhaler and spacer or *via* a dry-powder inhaler is as effective in patients with moderately severe acute asthma [81, 82] and avoids the risk of disseminating infectious particles. Current evidence does not support the routine use of intravenous β_2 -agonists in patients with severe asthma exacerbations [83].

Start OCS early after presentation. For adults, give prednisolone 40–50 mg per day (or equivalent) for 5–7 days. For children, give prednisolone 1–2 mg·kg⁻¹ (maximum, 40 mg) for 3–5 days. Tapering is not needed if administered for <2 weeks.

FIGURE 5 Management of asthma exacerbations in primary care (adults, adolescents, children 6–11 years). SABA doses are for albuterol. Reproduced by permission from reference 4 (box 4-3). PEF: peak expiratory flow; pMDI: pressurized metered-dose inhaler; SABA: short-acting β_2 -agonist.

Review response of symptoms, vital signs, oxygen saturation and lung function after 1 h (or earlier if worsening). Give ipratropium bromide only for severe exacerbations. Consider intravenous magnesium sulfate for patients with severe exacerbations not responding to initial treatment.

Do not routinely request chest radiography or routinely prescribe antibiotics for asthma exacerbations.

The decision on whether to hospitalize should be based on the patient's clinical status, lung function, response to treatment, recent and past history of exacerbations, social support, and ability to manage at home.

Rationale

Currently, inhaled albuterol is the usual bronchodilator in acute asthma management. Similar efficacy and safety of formoterol in the ED have been reported [84]. In one study, high-dose budesonide–formoterol had similar efficacy and safety to SABA in ED patients [85].

Discharge management

Before the patient goes home, arrange ongoing treatment. This should include starting ICS-containing controller treatment, preferably ICS–formoterol as MART (table 1; table E2 and downloadable resource in the supplementary material) to reduce the risk of another exacerbation, or stepping up the dose of existing maintenance treatment for 2–4 weeks. Advise patients to use reliever medication as needed, not regularly. Patients prescribed ICS–formoterol as their reliever should return to this after an ED presentation.

Follow-up

Arrange early follow-up after any exacerbation, regardless of where it was managed:

- Review the patient's symptom control and risk factors for further exacerbations.
- Prescribe/continue ICS-containing controller therapy (preferably MART with ICS–formoterol) to reduce the risk of further exacerbations. If already taking controller therapy, continue increased doses for 2–4 weeks.
- Provide a written asthma action plan and, where relevant, advice about avoiding exacerbation triggers.
- Check inhaler technique and adherence.

Asthma outcomes after an ED presentation for acute asthma are significantly improved by comprehensive intervention programmes that include optimal controller management, inhaler technique, and elements of self-management education (self-monitoring, written action plan, and regular review) [86, 87].

Referral for expert advice should be considered for patients who have been hospitalized for asthma or who have repeat presentations to acute care settings. Follow-up by a specialist is associated with fewer subsequent ED visits or hospitalizations and better asthma control [87].

Diagnosis and initial treatment of asthma in children 5 years and younger

Diagnosis

Recurrent wheezing occurs in a large proportion of children 5 years and younger, typically with viral respiratory infections. Recognising when this is the initial presentation of asthma is difficult. In young children with a history of wheezing, a diagnosis of asthma is more likely if they have any of the following:

- Wheezing or coughing that occurs with exercise, laughing, or crying, particularly in the absence of an apparent respiratory infection.
- Allergic sensitization, eczema, allergic rhinitis or food allergy, or asthma in first-degree relatives.
- Clinical improvement during 2–3 months of controller treatment and worsening after cessation.

It is particularly important in this age group to consider and exclude alternative causes of wheeze, cough, and breathlessness (box 6-3 in reference 4).

Important indications for referral of children ≤ 5 years for further diagnostic investigations include neonatal/very early onset of symptoms, failure to thrive, continuous wheezing, symptoms not associated with typical triggers (e.g. viral respiratory infections), or associated with vomiting, focal lung or cardiovascular signs, finger clubbing, hypoxaemia outside the context of viral illness, or failure to respond to asthma medications.

Initial treatment

The goals of asthma management in young children are to achieve good control of symptoms and maintain normal activity levels and to minimize the risk of asthma exacerbations, impaired lung development, and medication side effects.

Children 5 years and younger

Personalized asthma management:

Assess, Adjust, Review response

Asthma medication options:

Adjust treatment up and down for individual child's needs

PREFERRED CONTROLLER CHOICE

Other controller options

RELIEVER

CONSIDER THIS STEP FOR CHILDREN WITH:

	STEP 1	STEP 2	STEP 3	STEP 4
		Daily low dose inhaled corticosteroid (ICS) (see table of ICS dose ranges for pre-school children)	Double 'low dose' ICS	Continue controller & refer for specialist assessment
		Daily leukotriene receptor antagonist (LTRA), or intermittent short courses of ICS at onset of respiratory illness	Low dose ICS + LTRA Consider specialist referral	Add LTRA, or increase ICS frequency, or add intermittent ICS
	As-needed short-acting β_2 -agonist			
	Infrequent viral wheezing and no or few interval symptoms	Symptom pattern not consistent with asthma but wheezing episodes requiring SABA occur frequently, e.g. ≥ 3 per year. Give diagnostic trial for 3 months. Consider specialist referral. Symptom pattern consistent with asthma, and asthma symptoms not well-controlled or ≥ 3 exacerbations per year.	Asthma diagnosis, and asthma not well-controlled on low dose ICS Before stepping up, check for alternative diagnosis, check inhaler skills, review adherence and exposures	Asthma not well-controlled on double ICS

FIGURE 6 Personalized management of asthma in children 5 years and younger. Reproduced by permission from reference 4 (box 6-5). ICS: inhaled corticosteroid; LTRA: leukotriene receptor antagonist; SABA: short-acting β_2 -agonist.

Wheezing episodes in young children should be treated initially with inhaled SABA, regardless of whether the diagnosis of asthma has been made. However, SABAs are generally ineffective for initial episodes of wheeze in children younger than 1 year with infectious bronchiolitis.

A trial of controller therapy (e.g. for 3 months) should be given if the symptom pattern suggests asthma, alternative diagnoses have been excluded, and respiratory symptoms are uncontrolled and/or wheezing episodes are frequent or severe (figure 6). The response to treatment should be reviewed before deciding whether to continue it. If the response is absent or incomplete, reconsider alternative diagnoses.

It is important to discuss controller treatment choices with the child's parent/caregiver to explain the relative benefits and risks of treatment and the importance of maintaining normal activity levels for their child's physical and social development.

The choice of inhaler device should be based on the child's age and capability. The preferred device is a pressurized metered-dose inhaler and spacer, with a face mask for children younger than 3 years and a mouthpiece for most aged 3–5 years. Children should be switched from a face mask to a mouthpiece as soon as they can demonstrate good technique.

Review the need for asthma treatment frequently, as asthma-like symptoms remit in many young children or may be markedly seasonal. Measure the child's height at least once every year.

Asthma treatment steps for children 5 years and younger

Step 1

Provide inhaled SABA for relief of wheezing episodes. A need for SABA more than twice a week on average over 1 month indicates the need for a trial of controller medication.

Step 2

The preferred option is regular, daily, low-dose ICS plus as-needed SABA, given for at least 3 months (see box 6-6 in reference 4 for ICS doses). Regular montelukast is less effective than low-dose ICS, and parents/caregivers should be counselled about potential neurobehavioural adverse effects, as in a boxed warning from the US Food and Drug Administration [88].

Step 3

Before considering step-up to double the “low” ICS dose, check for concomitant or alternative diagnoses, check and correct inhaler technique and adherence, and ask about risk factors such as exposure to allergens or tobacco smoke. ICS-LABA is not recommended in children <4 years old, as there are insufficient data about efficacy and safety.

Step 4

Refer the child for expert advice if symptoms and/or flare-ups persist, or at any time if side effects of treatment are observed or suspected, or if there are doubts about diagnosis. See chapter 6 in reference 4 for details about other therapeutic options.

Managing exacerbations in children 5 years and younger

Early symptoms of exacerbations in young children may include increased symptoms, increased coughing (especially at night), lethargy or reduced exercise tolerance, impaired daily activities including feeding, and a poor response to reliever medication.

Managing exacerbations at home

Give a written asthma action plan to parents/caregivers of young children with asthma so they can recognise an impending exacerbation, start treatment, and identify when urgent hospital treatment is required. Initial treatment at home is with inhaled SABA, with review after 1 h or earlier. If inhaled SABA is needed more often than every 3 h or for >24 h, treatment by a health provider is needed on the same day. Parents/caregivers should seek urgent medical care if the child is acutely distressed, lethargic, fails to respond to initial bronchodilator therapy, or is worsening, especially in children younger than 1 year.

Rationale

Most children with wheezing due to asthma respond to SABA. There is insufficient evidence for parent-initiated OCS in this age group. Pre-emptive, episodic, parent-initiated high-dose nebulized ICS may reduce exacerbations in children with intermittent virally triggered wheezing [89], but there are no long-term studies, and there is a high risk of side effects; it should only be considered if the clinician is confident that it will be used appropriately and that the child will be monitored closely for side effects.

Managing exacerbations in primary care or acute care facility

Assess the severity of the exacerbation while initiating treatment with SABA (2–6 puffs every 20 min for first hour) and controlled oxygen to maintain a saturation of 94–98%. Arrange immediate transfer to a hospital if the child shows no response to inhaled SABA within 1–2 h, is unable to speak or drink, has a respiratory rate >40 breaths per min or is cyanosed, has oxygen saturation <92% on room air, or cannot be safely cared for at home.

For children attending an ED or admitted to hospital with asthma, consider systemic corticosteroids: oral prednisone/prednisolone 1–2 mg·kg⁻¹ per day for up to 5 days (maximum of 20 mg per day for children 0–2 years and 30 mg per day for children 3–5 years) or dexamethasone 0.6 mg·kg⁻¹ per day for 2 days.

Follow-up

Children who have experienced an asthma exacerbation are at risk of further exacerbations. Arrange follow-up within 1–2 days of an exacerbation and again 1–2 months later to identify modifiable risk factors and exacerbation triggers, optimize ongoing asthma management, and check inhaler technique and adherence.

Primary prevention of asthma in children

The development and persistence of asthma are driven by gene–environment interactions. For children, a “window of opportunity” to prevent asthma exists *in utero* and in early life, but intervention studies are limited. Current advice and recommendations for preventing asthma in children, based on high-quality evidence [90, 91] or consensus, include the following:

- Avoid exposure to environmental tobacco smoke during pregnancy and after birth.
- Encourage vaginal delivery where possible.

- Where possible, avoid the use of acetaminophen (paracetamol) and broad-spectrum antibiotics during the first year of life.
- Identification and correction of vitamin D insufficiency in women with asthma who are pregnant, or planning pregnancy, may reduce the risk of early-life wheezing episodes, but not asthma.
- Allergen avoidance strategies directed at a single allergen have not been effective in preventing asthma. Multifaceted strategies may be effective, but the essential components have not been identified.

Breast-feeding is advised for its general health benefits.

Implementation of asthma management strategies into health systems

To improve asthma care and patient outcomes, evidence-based recommendations must be disseminated and implemented nationally and locally and integrated into health systems and clinical practice [92]. Implementation requires an evidence-based strategy involving professional groups and stakeholders and considering local cultural and socioeconomic conditions. The cost-effectiveness of implementation programs should be assessed so a decision can be made to pursue or modify them. Local adaptation and implementation of asthma care strategies are aided by purpose-developed tools [92].

Asthma management in low-resource settings

GINA 2021 is a global strategy relevant to the care of all children, adolescents, and adults with asthma, wherever they live. Most of the global burden of asthma morbidity and mortality occurs in low-income and middle-income countries [1, 93] because of lack of necessary resources for effective long-term asthma care [1, 93, 94]. GINA has identified ongoing lack of access to ICS as a serious concern [4], especially as they can be produced at low cost. The safest and most effective approach to asthma treatment in adolescents and adults, which also avoids the consequences of starting treatment with SABA alone, depends on access to ICS–formoterol across all asthma severity levels [4]. However, despite listing of budesonide–formoterol on WHO's Essential Medicines List [95], affordable access is very limited in many low-resource settings [1, 4, 93, 94, 96]. The urgent need to ensure access to affordable, quality-assured inhaled asthma medications as part of universal health coverage must now be prioritized by all relevant stakeholders, particularly manufacturers of inhalers on the WHO Essential Medicines List [95].

Topics requiring further research

In addition to ongoing evidence reviews across the whole asthma strategy, GINA plans to review the following topics:

- The definition of mild asthma.
- Assessment of symptom control in patients whose reliever is ICS–formoterol.
- Subcutaneous and sublingual allergen immunotherapy.
- The diagnosis and management of asthma in preschool children.
- The use of digital tools and communication in asthma management.
- Management of asthma in low- and middle-income countries.

GINA also plans to develop a pocket guide for severe asthma in children 6–11 years. COVID-19 advice on the GINA website will be updated as new evidence emerges.

Acknowledgement: The authors thank Rebecca Decker, GINA Executive Director, and Kristi Rurey, GINA Project Manager, for supporting and coordinating the GINA Science Committee and Board, Dr. Ruth Hadfield for assistance with literature research, GINA Advocates and Assembly members across many countries for identifying clinicians' needs and concerns, Kate Chisnall for assistance with graphics, and Jennifer Harman for editorial assistance. They thank Richard Beasley, Alan Kaplan, Hugo Neffen, Michael Schatz, Hesham Tarrif, and Richard van Zyl-Smit for their helpful review of the manuscript. They acknowledge the outstanding and dedicated work of Dr. Suzanne Hurd as Scientific Director of GINA and Dr. Claude Lenfant as Executive Director, from the inception of GINA in 1993 until their retirement in 2015.
