## **Abstract**

Pulmonary arterial hypertension (PAH) is a progressive disease predominantly targeting pre-capillary blood vessels. Adverse structural re-modelling and increased pulmonary vascular resistance result in cardiac hypertrophy and ultimately failure of the right ventricle. Recent whole genome and exome sequencing studies have identified *SOX17* as a novel risk gene in PAH, with a dominant mode of inheritance and incomplete penetrance. Rare deleterious variants in the gene and more common variants in upstream enhancer sites have both been associated with the disease and a deficiency of *SOX17* expression may predispose to PAH. This review aims to consolidate the evidence linking genetic variants in *SOX17* to PAH and explores the numerous targets and effects of the transcription factor, focussing on the pulmonary vasculature and the pathobiology of PAH.

## Introduction

Pulmonary arterial hypertension (PAH) is a rare condition characterised by structural remodelling of pulmonary arterioles and arteries, endothelial dysfunction, proliferation of mesenchymal cells in the vessel wall and inflammation [1]. About a third of patients with PAH are classified as idiopathic, heritable, or drug-induced and the annual mortality, even in the most experienced treatment centres and with a typical age at diagnosis in the mid-forties, averages 10% [2]. Despite common features in the vascular pathology, there is evidence of heterogeneity among these patients, as seen in the individual response to specific drugs and in the emerging underlying genetic architecture [3].

A major breakthrough in our understanding of the pathobiology of PAH was the discovery two decades ago of heterozygous germline mutations in the gene encoding the bone morphogenetic protein type II receptor (*BMPR2*), a member of the transforming growth factor- $\beta$  (TGF $\beta$ ) super-family [4, 5]. Mutations in *BMPR2* are recognised as the most common cause of PAH, occurring in approximately 70% of heritable (HPAH) and 10–20% of idiopathic (IPAH) cases, and their discovery has suggested potential therapies designed to enhance BMP signalling in PAH [6]. In addition to *BMPR2*, at least 16 other genes have now been implicated in the genetic architecture of PAH [3, 7]. These include mutations in TGF- $\beta$  related genes, such as activin receptor type II-like 1 (*ACVRL1*), endoglin (*ENG*), BMP receptor type 1A (*BMPR1A*) and type 1B (*BMPR1B*), as well as variants in caveolin-1 (*CAV1*), eukaryotic initiation translation factor 2 alpha kinase 4 (*EIF2AK4*), potassium subfamily K member 3 (*KCNK3*), SMAD family members 4 and 9 (*SMAD4* and *SMAD9*), and T-box4 (*TBX4*) [3, 7]. Deleterious variants in other previously unidentified genes were recently found in a large-scale European study in PAH, encoding the transcription factor SRY-box 17 (*SOX17*), ATPase 13A3 (*ATP13A3*), aquaporin 1 (*AQP1*) and growth differentiation factor 2/BMP9 (*GDF2*) [8]. The evidence level for the causal role of mutations in a particular gene needs to be high for it to be used for clinical screening and this has not yet been met for *SMAD4*, *SMAD1*, *KLF2*, *BMPR1B* and *KCNA5* [7]. Most recently, evidence has been presented for *BMP10* [9, 10] and *KDR* [11, 12] as novel PAH genes. With the exception of *EIF2AK4* which is associated with PVOD in a recessive manner, mutations in all these PAH associated genes are inherited in an autosomal dominant manner and exhibit reduced penetrance, suggesting that additional genetic, epigenetic and/or environmental factors are involved in modifying the development and progression of the disease [7].

## SOX family of transcription factors

The SRY-related HMG-box (SOX) family of transcription factors was first described for its role in sex determination and its members are now known to be critical regulators of development and regeneration. The family is characterized by a highly conserved HMG-box (high mobility group) DNA-binding domain and includes 20 members, almost all showing ~ 50% sequence homology to the HMG-box domain of the *SRY* gene [13, 14]. The SOX family is divided into subgroups (SoxA to SoxH) according to sequence homology and functional characteristics. Sox17 belongs to the SoxF sub-group, which also includes Sox7 and Sox18 [15]. Members of this group have been shown to be essential regulators of several

developmental processes, with Sox17 most prominent in the formation of the definitive endoderm and gastro-intestinal tract [16, 17], cardiovascular development [18] and pulmonary vascular morphogenesis [19]. Sox17 also plays a key role in priming haemogenic potential in endothelial cells and regulating haematopoietic development from human embryonic and induced pluripotent stem cells [20, 21].

The human *SOX17* gene was sequenced in 2002, localized to chromosome 8q12-q13 (now more specifically 8q11.23). It comprises two exons, with transcripts demonstrated in adult human heart, lung, spleen, testis, ovary, and placenta, in fetal lung and kidney and in the gastrointestinal tract [22]. The deduced 414-amino acid protein shares 41% and 43.5% identity with Sox7 and Sox18, respectively, and contains an HMG box domain located close to the N-terminus and  $\beta$ -catenin-binding domain in the C-terminal region. *SOX17* is also an important downstream transcriptional target of the Wnt/ $\beta$ -catenin pathway [13]. The HMG domain forms an L-shaped region composed of three helices and includes a signature amino acid sequence (RPMNAFMVW) that mediates binding to consensus motifs in the minor groove of the DNA helix, causing DNA bending and the formation of nucleoprotein complexes [13]. Sox proteins generally also require the binding of partner transcription factors to elicit transcriptional activation or repression and for the SoxF subgroup this includes specific factors that belong to the POU/OCT and PAX protein families [23, 24]. While in development *SOX17* is more widely expressed in healthy adult tissues, including the lung, [19], it displays an endothelial-specific profile.

### ***SOX17* in disease**

Variants of *SOX17* were first described in patients with congenital abnormalities of the kidney and urinary tract. Over-accumulation of the mutated protein (*SOX17*-p.Y259N) is associated with vesicoureteral reflux and attributed to its ability to inhibit the canonical Wnt/ $\beta$ -catenin signalling pathway [25]. However, the missense variant (c.775T>A, p.Tyr259Asn), which caused excessive accumulation of the Sox17 protein *in vitro*, was subsequently found in an individual without the associated congenital phenotype, leading to the suggestion that this and other *SOX17* missense variants outside the HMG domain may represent 'at-risk' rather than causative alleles [26]. Some of these correspond to polymorphisms in the promoter (rs55815819:C>T), in the 5' UTR (rs62516525:C>T) and in the 3' UTR (rs117273864:T>G). Others were identified in the coding sequence: c.479C>T (p.Ala160Val), c.775T>A (p.Tyr259Asn), c.942G>A (p.Gln314Gln) and c.971\_972dupGCACCA(p.His325insGlnHis). Susceptibility to intracranial aneurysm (**Figure 2**) has also been linked to SNPs on chromosome 8q and Sox17 signalling [27]. *SOX17* is the only gene in the 8q interval, located between two association peaks at 43 kb from rs10958409 and 64 kb from rs9298506. Endothelial-specific deletion of *SOX17* leads to impaired EC junctional assembly, cell-matrix adhesion, regeneration capacity, and paracrine secretion and aneurysm formation in hypertensive mice [28]. Numerous studies have implicated *SOX17* in cancer, many indicating that it acts as a tumour suppressor. Multiple mechanisms are reported to downregulate *SOX17* expression in human tumours, including chromosome loss and dysregulation by microRNAs and long non-coding RNAs, but accumulating evidence

suggests that DNA hypermethylation plays the dominant role [29]. Indeed, *SOX17* hypermethylation may be a useful molecular biomarker for the detection and diagnosis of various tumours, predicting response to therapy and prognosis [29]. In contrast, high *SOX17* expression drives tumour angiogenesis and suppression in tumour endothelium may be beneficial [30].

### Rare deleterious *SOX17* variants in PAH

In contrast to vesicoureteral reflux in which elevated *SOX17* levels/accumulation has been observed, all PAH associated variants predict loss of function, emphasising that tight control of *SOX17* is required to avoid a variety of pathological phenotypes. They are also distinct from variants associated with other diseases. Recently, *SOX17* heterozygous variants were associated with PAH (**Figure 2**) [8, 31]. As part of the UK National Institute for Health Research BioResource (NIHRBR) Rare Diseases project [32], a whole genome sequence case-control analysis was conducted on 1,038 patients with idiopathic, heritable and anorexigen-associated PAH, demonstrating statistically significant enrichment of rare deleterious variants in *SOX17*, *ATP13A3*, and *AQP1* [8]. This was picked up by SKAT-O test following protein-truncating variants (PTVs) impact analysis, with exclusion of rare variants and deletions in previously reported PAH genes, such as *BMP2*, to unmask novel causative genes. The heritability ascribed to each gene was relatively low, with *SOX17* variants representing ~0.9% of the overall cohort. Both *SOX17* and *AQP1* mutation carriers had a significantly younger age at diagnosis and the variants segregated with the phenotype in available pedigrees [8]. The *SOX17* variants included nonsense variants, predicted to lead to loss of the  $\beta$ -catenin binding, and missense variants predicted to disrupt interactions with  $\beta$ -catenin and the transcription factor OCT4 (**Figure 1**). Missense variations in the conserved HMG box domain are also likely to affect Sox17 DNA binding and lead to loss-of-function defects. In lung tissue sections, Sox17 was predominantly localised to the pulmonary endothelium and *in vitro* was highly expressed in pulmonary endothelial and blood outgrowth endothelial cells compared with pulmonary smooth muscle cells [8].

Independent whole exome sequencing studies have also implicated *SOX17* mutations as a risk factor in patients with PAH-associated congenital heart disease (PAH-CHD) [31]. Rare deleterious variants contributed to ~3.2% of the 256 PAH-CHD cases studied, compared to ~0.7% in a separate group of 413 IPAH/HPAH patients, and included missense variants in the HMG-box domain (**Figure 1**). *SOX17* variants were additionally linked to a lower mean age of onset at 26 years compared to 41-46 years in pathogenic *KCNA5*, *ATP13A3*, and *SMAD1* variant carriers. Rare predicted deleterious variants were observed in only 5/7509, 0.07% of controls, and without characterisation of specific variants it is unknown whether they are functional. The study also noted an enrichment of 163 rare deleterious variants among 149 putative targets of Sox17, with most expressed in the developing murine heart and/or adult human pulmonary artery endothelial cells [31]. Another whole exome sequencing study found four (3 unrelated) *SOX17* variant carriers among 140 Japanese IPAH/HPAH patients, where one patient's healthy mother also carried the variant emphasising the incomplete penetrance in PAH [33]. Similar analysis of 2,572 cases in the US National Biological Sample

and Data Repository for PAH reported rare deleterious *SOX17* variants in 10 patients, again with a significantly younger mean age of disease onset [34].

### **Common variants upstream of the *SOX17* gene in PAH**

Common variants contribute to complex and multifactorial diseases, but the impact of common genetic variation on the risk of developing PAH and its natural history has not been widely explored. The largest genome-wide association study (GWAS) to date included two separate analyses and cross-validation of loci reaching genome-wide significance by meta-analysis, using data from four international case-control studies across 11,744 individuals with European ancestry and included 2,085 patients with PAH [35]. One analysis used genotypes from 5,895 whole-genome sequences and the other used genotyping array data from an additional 5,849 individuals. A locus 100–200 kb upstream of *SOX17* (rs10103692, odds ratio 1.80 [95% CI 1.55–2.08],  $p=5.13 \times 10^{-15}$ ) in regions characterised by enhancer epigenomic markers in endothelial cells was found to associate with PAH. Conditional analysis showed that it comprised two independent signals; located 100–103 kb (signal 1) and 106–200 kb (signal 2) upstream of *SOX17*, respectively. The lead SNPs for the two signals were rs13266183 (signal 1, odds ratio 1.36 [1.25–1.48],  $p=1.69 \times 10^{-12}$ ) and rs10103692 (signal 2). The functional effect of the novel *SOX17* locus on PAH susceptibility was further confirmed by examining protein/DNA complexes and chromatin interaction using Hi-C technology to determine DNA folding patterns. The first signal at locus rs13266183 was shown by CRISPR-mediated inhibition of the enhancer to exclusively regulate *SOX17*, reducing *Sox17* expression in human pulmonary artery endothelial cells. When the rs13266183 region was transfected into these cells, 3–6-fold induction in luciferase reporter assays confirmed allele-specific enhancer activity.

Importantly, the *SOX17* genotype did not associate with survival. Impairment of *SOX17* function might be more common in PAH than suggested by rare mutations in the gene itself, and we anticipate that *SOX17* has a role in susceptibility to the disease [35]. As the initiation of the pathophysiological processes in PAH remains an enigma, the discovery of *SOX17* may direct further research to elucidate the early beginnings of PAH.

### **Roles of *SOX17* in cardiovascular and pulmonary vascular development and homeostasis**

The three *SoxF* transcription factors have distinct as well as overlapping roles in cardiovascular development and postnatal neovascularisation (**Figure 2**). *SOX17* is necessary for the formation and maintenance of the endoderm [36] and comparative analyses of embryonic cardiovascular phenotypes in *SOX17/SOX18*-double and *SOX17*-single knockout mice indicated redundant roles for *SOX17* and *SOX18* in the formation of anterior dorsal aorta and differentiation of endocardial heart tube, with anomalies in anterior vascular formation corresponding with the sites of low *SOX7* expression [37]. In the early embryo, *Sox17* expression is localized in the endoderm. It then increases in the dorsal aorta during vascular development and is subsequently preferentially expressed in arterial vascular endothelial and not venous cells [38]. *SOX17* has a distinct role in developing and maintaining arterial endothelial cell specificity, compared to the broader functions of *SOX7* and *SOX18* in the vasculature [31]. Whereas *SOX17* and *SOX18* are both required in vascular endothelial cells for postnatal angiogenesis [39], low *Sox17* and high *Sox7/Sox18* levels are

essential for systemic vein development and maintenance (Duong et al., 2014). Sox18 is specifically required for lymphatic development [36].

*SOX17* is required for the normal formation of the pulmonary vasculature and postnatal cardiovascular homeostasis (**Figure 2**). The knockout of *SOX17* in developing pulmonary vascular endothelial cells (splanchnic mesenchyme-specific knockout using a Dermo1-Cre) has potent effects on vascular development and causes perinatal defects. The abnormalities before birth include pulmonary vein varices, enlarged pulmonary arteries, and decreased perfusion of the lung microvasculature, with alveolar simplification, biventricular cardiac hypertrophy, and valvular regurgitation after birth [19].

The stability and permeability of the blood vessel wall in the lung relies on vascular endothelial (VE)-cadherin [40] and endothelial cell-selective adhesion molecule (ESAM) [41] and the genes for both proteins contain consensus sequences for Sox17 in their promoters [42]. Sox17 has also been shown to be a key player in multiple signalling pathways of relevance to PAH including Transforming Growth Factor-beta (TGF- $\beta$ ) signalling, BMPs, Wnt- $\beta$ -catenin, Notch and VEGF signalling, which are themselves interlinked (**Figure 3**).

#### **Sox17 in disease pathways related to PAH**

Sox17 targets, such as nicotinamide phosphoribosyltransferase (NAMPT) and nestrin, have been implicated in PAH. Extracellular NAMPT is a proinflammatory cytokine that promotes endothelial to mesenchymal transition and pulmonary vascular remodelling [43]. Sox17 and Sox18 exhibit opposing effects on endothelial NAMPT expression; silencing of *SOX17* results in attenuation of VEGF-induced NAMPT promoter activity whereas silencing of *SOX18* has the opposite effect [43]. Nestrin is a type IV intermediate filament that regulates sprouting and remodelling of the developing coronary vasculature [44]. Interestingly, nestrin has been found in proliferating VSMCs, notably during the development of experimental pulmonary hypertension, as well as in the media and neointima in human pulmonary vascular lesions [45]. Nestrin is also localized to the endothelium in pulmonary vascular lesions and implicated in endothelial proliferation and angiogenesis in PAH [46].

**Sox17 and endothelin.** The endothelin-converting enzyme-1 (ECE-1) gene is a central component of the endothelin signaling pathway, being required for embryonic development and regulation of vascular tone. It is under the control of forkhead and ETS-domain transcription factors, specifically FOXC2 and ETV2, that act synergistically via a FOX:ETS motif [47]. Unlike other FOX:ETS-dependent enhancers, ECE1 expression is restricted to the embryonic arterial endothelium and endocardium and the enhancer region is bound and activated by Sox17, which functions together with FoxC2 and Etv2 to promote ECE1 expression ([47]. Endothelin-1 (ET-1) is a potent vasoconstrictor peptide derived from the endothelium, and demonstrates increased expression in the lungs of PAH patients, notably in endothelial cells of pulmonary arteries with medial thickening and intimal fibrosis [48]. There is a strong correlation with elevated plasma levels of ET-1 and PAH phenotypes,

such as pulmonary vascular resistance, mean pulmonary artery pressure, cardiac output, cardiac index, 6-min walk data [49]. Endothelin receptor antagonism is a validated therapeutic strategy for PAH. The effects of perturbation of Sox17 could well be mediated, in part, through the endothelin pathway.

**Sox17 and TGF- $\beta$ .** Sox17 has various cell cycle mediating functions via TGF- $\beta$  signalling. TGF- $\beta$  is a potent inhibitor of proliferation in multiple epithelial cell types, including alveolar type II cells [50]. This anti-proliferative effect has been linked to Smad-dependent transcriptional induction of cyclin-dependent kinase inhibitors. These include p15 and p21 and their induction leads to G<sub>1</sub> phase arrest. In the adult mouse lung, Sox17 decreased the expression of cell cycle inhibitors p15, p21 and p57 [51]. Co-immunoprecipitation assays showed that Sox17 interacts with Smad3, thereby inhibiting TGF- $\beta$ 1-mediated transcription [52]. Inactivation of Smad2/3 or Smad4 causes downstream loss of expression of TGF- $\beta$  target genes (including S1PR1 and N-cadherin) in mouse endothelial cells and results in vascular defects [20, 52, 53]. Rare variants of endoglin and beta-glycan, both type III receptors for TGF- $\beta$  pathway, have been associated with intracranial aneurysm [54]. Loss of Sox17 expression has been linked to disruption of cell-cell adhesion via its modulation of VE-cadherin in precursor endothelial cells [20]. This mechanism could also be of relevance to aneurysm development. Within the context of endothelial to haematopoietic transition, Sox17 becomes a downstream effector of activated TGF- $\beta$  signalling, where increased Sox17 expression impairs transition and blocks commitment to haematopoietic lineage [51]. As such, Sox17 is a key player in contributing to TGF- $\beta$  signalling and affects the proliferation of both pulmonary epithelial and haematopoietic cells.

**Sox17 and BMPs.** BMPs are highly conserved throughout evolution and account for 20 of the 33 known members of the TGF- $\beta$  superfamily in humans [55]. BMPs are usually secreted as active dimeric complexes and some, like BMP9, are bound to a prodomain. As well as *BMPR2*, rare, inactivating mutations in *GDF2* (encoding BMP9) have recently been associated with PAH development [8]. BMP signalling represses Sox17 expression whereas TGF- $\beta$  signalling activates Sox17 in endodermal development in the Zebrafish [56]. In contrast, BMP2 and Sox17 form a positive feedback loop that triggers lineage commitment in human embryonic and induced pluripotent stem cells to become cardiac progenitors; BMP2 and Oct4 upregulate Sox17 expression [57]. Sox17 then promotes further expression and accumulation of BMP2 driving cardiogenesis. Sox17 and BMP2 demonstrated reciprocal induction in embryonic stem cells made resistant to cardiac differentiation by HDAC1-knockdown, returning expression to levels comparable to WT cells [57]. BMPs and Sox17 also overlap in their signalling effector molecules with common effects on vascular development and homeostasis pathways, including VEGF, Notch, Smad and Wnt signalling [58]. Sox17 and BMP9 share the same regulators and downstream effectors. BMP9 suppresses VEGF expression and VEGF-induced angiogenesis via ALK1 and BMPR2 signalling [55], which contrasts with promotion of VEGF signalling by Sox17. BMP9 treatment of endothelial cells resulted in restriction of apoptosis by inhibiting TNF- $\alpha$ -induced phosphorylation of JNK and prevented the loss of monolayer integrity driven by treatment

with LPS [59]. Likewise, Sox17 is a key player in cell-cell adhesion and vascular endothelial remodeling. Whether or not one of the key features of loss of *SOX17* in heritable cases is an imbalance in TGF-beta and BMP signalling, associated with dysfunctional pulmonary vascular homeostasis, is a topic worthy of further studies.

**Sox17 and Wnt/ $\beta$ -catenin.** Sox17 influences the regulation of cell proliferation and migration via Wnt/ $\beta$ -catenin signalling. Sox17 expression is linked to progression and prognosis of various forms of cancer, including colon cancer and endometrial cancer [60]. Sox17 is antagonistic to Wnt signalling in this context, displaying a tumour suppressor effect; the over-expression of Sox17 in SW480 colon carcinoma cells inhibited  $\beta$ -catenin/TCF activity in a dose-dependent manner and reduced proliferation [61]. Sox17 inhibited the canonical Wnt pathway by forming a complex with TEF/LEF and  $\beta$ -Catenin and targeting them for GSK3 $\beta$ -independent degradation (**Figure 3**). A decrease in Sox17 levels has also been linked to endometrial cancer development and progression, accompanied by increased Wnt signalling [62]. Sox17 inhibits cell migration by inactivating the Wnt/ $\beta$ -catenin–epithelial mesenchymal transition axis in endometrial cancer cells [63].

Endothelial-specific inactivation of Sox17 has profound effects on the vasculature. In the brain, it leads to increased permeability of the microcirculation. RNA expression analysis of brain endothelial cells in *SOX17* conditional knock-out mice has identified members of the Wnt/ $\beta$ -catenin signalling pathway, such as Nkd1 and Lef1, as downstream targets of Sox17 [40]. In this case, in contrast to studies of its role in cancer, Sox17 is a positive inducer of Wnt/ $\beta$ -catenin signalling and it acts in synchrony with this pathway to induce and maintain integrity of the blood brain barrier. In human ECs, the canonical Wnt pathway controls the expression of target genes, such as *c-myc*, *cyclin-D1*, *VEGF*, *survivin* and *axin2*, which are involved in cell maintenance, proliferation and survival [64–66] and *interleukin-8 (IL8)*, which is important in angiogenic regulation [67]. Sox17 was shown to play an essential role in cardiac muscle cell formation via interaction with the Wnt/ $\beta$ -catenin pathway, acting at a gastrulation-like stage, mediating mesoderm formation and patterning which are prerequisites for cardiac myogenesis [68].

**Sox17 and Notch signalling.** The Notch pathway is an important downstream target of Sox17, binding directly to regulatory loci and promoting expression of *Notch1*, *Notch4*, *Dll1*, and *Dll4* genes in adult vascular endothelial cells [38]. Knockout of *SOX17* not only reduces the expression of arterial-specific genes but also induces the expression of venous-specific genes such as receptor subfamily 2 group F member 2 (*NR2F2*). In other situations, the Notch pathway can antagonise Sox17 signalling, suppressing its endothelial expression at the post-transcriptional level and thereby restrict angiogenesis [69]. Sox17 is involved in regulating migration of human umbilical vein endothelial cells (hUVECs) via its interactions with Notch signalling (**Figure 3**); destabilizing endothelial junctions and rearranging cytoskeletal structure and upregulating expression of several genes preferentially expressed in tip cells for angiogenesis, including Ang2, PDGF- $\beta$ , and VEGFR2 [69]. In this context, Notch and Sox17 are antagonistic, and Sox17 expression is suppressed in stalk cells where Notch signalling is relatively high. The Notch pathway regulates Sox17 expression mainly at the

post-transcriptional level; activation of Notch in hUVECs by Delta-like ligand-4 markedly decreased Sox17 protein levels while mRNA levels were only moderately reduced [69]. In other instances, Sox17 can enhance Notch signalling. In the maintenance of hematopoietic stem and progenitor cells in mouse intra-aortic hematopoietic clusters, Sox17 directly binds to the *Notch1* promoter and induces expression of Notch1 and downstream activation of the Hes1 pathway [70].

**Sox17 and VEGF.** Sox17 involvement in the adult vasculature and PAH related signalling is a relatively new field. Previous studies have focused on the role of Sox17 in development and cancer. Vascular endothelial growth factor (VEGF) stimulates Sox17 expression in cultured human endothelial cells [71] and upregulation of Sox17 expression at the protein level promotes VEGF receptor type 2 (VEGFR2) expression in angiogenic vessels [72]. Sox17 is also more directly involved in a positive feedback loop with VEGF (**Figure 3**); VEGF upregulates Sox17 expression at the protein level in cultured endothelial cells via the mTOR pathway while Sox17 promotes VEGFR2 expression in angiogenic vessels [72]. VEGF promotes Dll4 expression, which in turn activates notch signaling and suppresses VEGFR2 expression. This is required to stabilise newly formed vessels [73, 74]. It underscores a link between loss of Sox17 and disrupted VEGF-regulated angiogenesis.

**Sox17 and cyclins.** Sox17 affects cell proliferation via cyclin signalling. A decrease in Sox17 levels with progression of endometrial cancer correlated with the increased expression of cyclin D1 across 30 tissue specimens[75]. In mature epithelial cell specification from progenitor cells and the cellular response to lung injury, Sox17 activates cell proliferation pathways involving cyclin E1 [76] and cyclin D1 [51]. Both are essential for the control of the cell cycle at the G<sub>1</sub>/S transition. Cyclin proteins are downstream signalling molecules for Notch3, which regulates vascular smooth muscle cells (SMC) switching between contractile and synthetic phenotypes and plays an important role in vascular remodelling, such as seen in PAH [77]. In chronic hypoxia-induced PAH mouse models, cyclin D1 expression is also elevated along with increased Notch3 expression in pulmonary vessels [78, 79]. In response to lung injury, endotoxemia activates hypoxia-induced factor 1 $\alpha$  (HIF-1 $\alpha$ ) and HIF-1 $\alpha$  transcriptionally activates Sox17 to mediate cyclin E1-dependent endothelial cell regeneration [76]. This is especially relevant to PAH, where normoxic activation of HIF1 $\alpha$  is also observed. It may be more accurate to define the role of Sox17 in cell proliferation as a homeostatic one to maintain a healthy status quo, which remains vulnerable to environmental and cell status triggers.

These pathways offer important clues as to how *SOX17* mutations and consequent loss of Sox17 expression and function might drive altered pulmonary endothelial function, but the variability in interactions between pathways in different cell and tissue types emphasises the importance of establishing their individual relevance and importance in pulmonary vascular cells. In particular, due to the importance of *BMPR2* in heritable PAH and the current development of therapeutics targeting BMP/TGF- $\beta$  signalling in this condition, a detailed analysis of the role of Sox17-BMP-TGF- $\beta$  functions in pulmonary endothelial cell function should be a priority. The availability of animal models of *SOX17* loss offers opportunities to test effects on PAH development in established systems including hypoxia.

As with *BMPR2*, the presence of patients with *SOX17* rare pathogenic variants suggests therapeutic strategies aimed at restoring *SOX17* could be an early focus.

## **Conclusion**

*SOX17* is essential for normal cardiac and pulmonary vascular development and animal models have demonstrated that disruption can produce phenotypes relevant to PAH. *SOX17* is specifically expressed in arterial endothelial cells in the lung and has emerged as a gene that delineates risk of PAH. Both rare and common genetic variation contributes to the disease. Indeed, Sox17 interacts with key signalling pathways and transcriptional targets that are known to be involved in the pathobiology of PAH. The restoration of *SOX17* expression and signalling may represent a new promising therapeutic strategy in PAH.

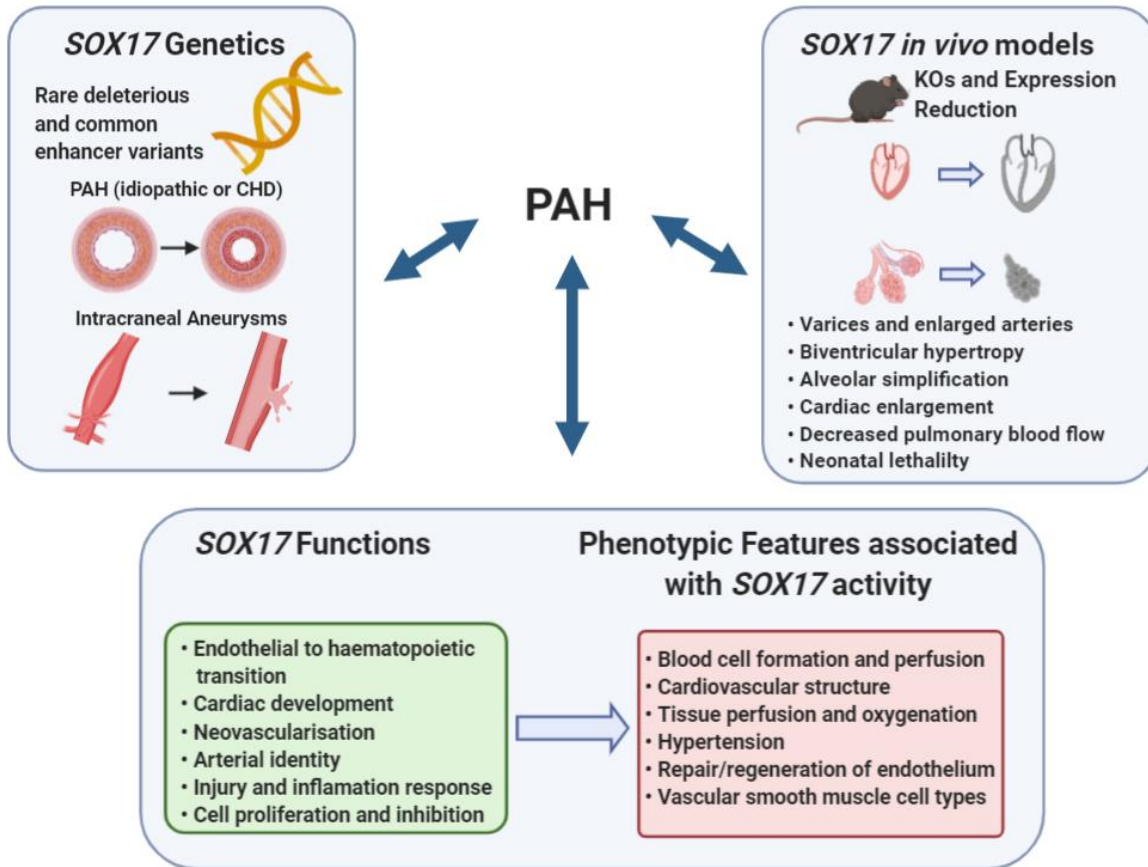

Figure 1 – Schematic of *SOX17* gene indicating variants identified by sequencing in PAH patients. [8, 31, 33, 34]. PTVs, protein truncating variants.

**Figure 2: Central Illustration:** Sox17 has been linked to PAH through genetic studies, and *in vivo* models have demonstrated its key role in pulmonary vascular development. As an endothelial-specific transcription factor, Sox17 acts through multiple signalling pathways and has functions relevant to the pathophysiology of PAH, identifying it, or downstream signalling, as a clear target for therapeutic investigations.

**Figure 3** – SOX17 related pathways in endothelial cells (EC) include **A. VEGF signaling**. The PI3K-AKT-mTOR pathway is important in cell survival and regulation of the barrier function and involves the activation of the SRC transcription factor through the phosphorylation of VEGFR2 at Y949. One of the downstream effects of this pathway is smooth muscle cell (SMC) vasodilation through activation of endothelial nitric oxide synthase [80]. VEGF signaling is regulated in ECs by the DII4-notch pathway. VEGF-induced angiogenesis is negatively regulated by Notch signaling, a pathway which Sox17 is potentially also negatively regulated by. **B. Canonical Wnt signaling pathway**. In the canonical Wnt

signaling pathway, the frizzled receptors (FZD) bind to low-density lipoprotein receptor-related protein 5/6 co-receptors (LRP5, LRP6) and form a cell surface complex [81]. In the absence of a Wnt ligand, this complex does not repress glycogen synthase kinase 3 $\beta$  (GSK3 $\beta$ ), which targets  $\beta$ -catenin for proteasome-mediated degradation through phosphorylation of serine residues. When the FZD/LRP5 receptor is bound, it represses the activity of GSK3 $\beta$  and  $\beta$ -catenin stabilises and relocates to the nucleus. The Sox17 protein has a similar HMG binding domain structure to T-cell factor/lymphoid enhancer factor (TCF/LEF) transcription factors and is well known to interact with  $\beta$ -catenin. **C. Notch signaling.** The notch receptor can be bound by notch ligands jagged1 and jagged2 (Jag1, Jag2) and delta-like protein (Dll)-1, Dll3 and Dll4 [82]. This causes the double cleavage of the notch receptor extracellularly by a disintegrin and metalloproteinase domain containing protein 10 (ADAM10) and intracellularly by  $\gamma$ -secretase which leads to the release of the notch intracellular domain (NICD). The NICD then travels into the nucleus where it has a transcription factor role.
